

# THS3217 直流至 800MHz、差分转单端、DAC 输出放大器

## 1 特性

- 输入级：2V/V 的内部增益
  - 经缓冲的差分输入
  - 单端低阻抗输出
  - 全功率带宽：500MHz (2 V<sub>PP</sub>)
- 输出级：可从外部配置增益
  - 全功率带宽：500MHz (5 V<sub>PP</sub>)
  - 转换率：5000V/μs
  - 单刀双掷 (SPDT) 输入开关/多路复用器
- 完整信号路径：输入级 + 输出级
  - 二次谐波 (HD2) (20MHz, 5V<sub>PP</sub> 接至 100Ω 负载)：-60dBc
  - 三次谐波 (HD3) (20MHz, 5V<sub>PP</sub> 接至 100Ω 负载)：-75dBc
  - 10V<sub>PP</sub> 输出接至 100Ω 负载，使用 ±6.5V 分离电源
  - 12V<sub>PP</sub> 输出接至高容性负载，使用 15V 单电源
- 内部直流 (DC) 基准缓冲器，具有低阻抗输出
- 电源范围：
  - 分离电源：±4V 至 ±7.9V
  - 单电源：8V 至 15.8V

## 2 应用

- 数模转换器 (DAC) 输出放大器
- 宽带任意波形发生器 (AWG) 输出驱动器
- 前置驱动器接至 > 20V<sub>PP</sub> 输出放大器 (THS3091)
- 适用于压电式元件的单电源、高容性负载驱动器

## 3 说明

THS3217 整合了连接互补电流输出数模转换器 (DAC) 时所需的关键信号链组件。此双级放大器系统极具灵活性，可广泛应用于各类系统中以提供低失真、直流耦合的差分转单端信号处理。输入级会对 DAC 电阻端进行缓冲，并以 2V/V 的固定增益对信号进行差分至单端转换。差分转单端输出可在外部直接使用，也可经 RLC 滤波器或衰减器连接至内部输出功率级 (OPS) 的输入端。宽带、电流反馈输出功率级可在外部为全部引脚灵活设置增益。

输出功率级同相输入内部连接有一个 2×1 多路复用器 (mux)，方便选择内部差分转单端级 (D2S) 输出或外部输入。

可选片上中间电压缓冲器提供了宽带、低输出阻抗电源，可在单电源运行期间通过信号路径级提供偏置。此功能可为运行电源电压最高为 15.8V 的应用提供非常简单的偏置方法。此缓冲器接外部输入后可实现直流纠错环路或简单的输出直流偏移功能。

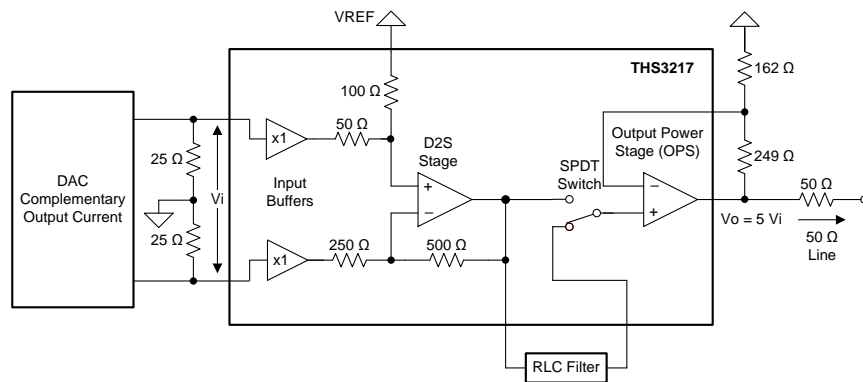

一款配套器件，THS3215，能够以更低的静态功率和带宽提供相同的功能特性。THS3217 和 THS3215 支持面向 AWG 应用的德州仪器 (TI) 新上市的高速 DAC，例如 DAC38J82。

器件信息<sup>(1)</sup>

器件型号	封装	封装尺寸 (标称值)
THS3217	VQFN (16)	4.00mm x 4.00mm

(1) 要了解所有可用封装，请参见数据表末尾的封装选项附录。

增益 = 5V/V，带可选外部滤波器的差分转单端线路驱动器

## 5 Device Comparison Table

DEVICE	SMALL-SIGNAL BANDWIDTH 0.1 V <sub>PP</sub> (A <sub>V</sub> = 5 V/V) <sup>(1)</sup>	LARGE-SIGNAL BANDWIDTH 5V <sub>PP</sub> (A <sub>V</sub> = 5 V/V)	QUIESCENT CURRENT, I <sub>CC</sub> (±6-V SUPPLIES)	TOTAL HARMONIC DISTORTION (5 V <sub>PP</sub> , R <sub>LOAD</sub> = 100 Ω, 20 MHz)	CONTINUOUS OUTPUT CURRENT	PEAK OUTPUT CURRENT
THS3217	800 MHz	500 MHz	55 mA	–60 dBc	110 mA	175 mA
<b>THS3215</b>	350 MHz	250 MHz	35 mA	–50 dBc	80 mA	125 mA

(1) A<sub>V</sub> is the voltage gain.

## 6 Pin Configuration and Functions

**Table 1. Pin Functions**

PIN		I/O	DESCRIPTION
NO.	NAME		
1	VMID_IN	Input	DC reference buffer input
2	+IN	Input	Positive signal input to D2S
3	–IN	Input	Negative signal input to D2S
4	PATHSEL	Input	Internal SPDT switch control: low selects the internal path, and high selects the external path
5	–VCC2 <sup>(1)</sup>	Power	Negative supply for input stage
6	VO1	Output	D2S external output
7	GND	Power	Ground for control pins reference
8	–VCC1 <sup>(1)</sup>	Power	Negative supply for output stage
9	VIN+	Input	External OPS noninverting input
10	DISABLE	Input	Output power stage shutdown control: low enables the OPS, and high disables the OPS
11	VOUT	Output	OPS output
12	VIN–	Input	OPS inverting input
13	+VCC1 <sup>(1)</sup>	Power	Positive supply for output stage
14	VREF	Input	DC offsetting input to D2S
15	VMID_OUT	Output	DC reference buffer output
16	+VCC2 <sup>(1)</sup>	Power	Positive supply for input stage
Thermal Pad		—	Connect the thermal pad to GND for single-supply and split-supply operation. See <a href="#">Thermal Considerations</a> section for more information.

(1) Throughout this document +V<sub>CC</sub> refers to the voltage applied at the +VCC1 and +VCC2 pins, and –V<sub>CC</sub> is the voltage applied at the –VCC1 and –VCC2 pins

## 7 Specifications

### 7.1 Absolute Maximum Ratings

over operating free-air temperature range (unless otherwise noted)<sup>(1)</sup>

		MIN	MAX	UNIT
Voltage	Supply, +V <sub>CC</sub> – (–V <sub>CC</sub> )		16.2	V
	Input/output	(–V <sub>CC</sub> ) – 0.5	(+V <sub>CC</sub> ) + 0.5	
	Differential input voltage (IN+ – IN–)		±8	
Current	Continuous input current (IN+, IN–, VMID_IN, VIN+, VIN–) <sup>(2)</sup>		±10	mA
	Continuous output current <sup>(2)</sup>		±30	
Temperature	Operating, T <sub>A</sub>	–55	105	°C
	Junction, T <sub>J</sub>	–45	150	
	Storage, T <sub>stg</sub>	–65	150	

(1) Stresses beyond those listed under *Absolute Maximum Ratings* may cause permanent damage to the device. These are stress ratings only, which do not imply functional operation of the device at these or any other conditions beyond those indicated under *Recommended Operating Conditions*. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.

(2) Long-term continuous current for electromigration limits.

### 7.2 ESD Ratings

		VALUE	UNIT
V <sub>(ESD)</sub> Electrostatic discharge	Human-body model (HBM), per ANSI/ESDA/JEDEC JS-001 <sup>(1)</sup>	±1500	V
	Charged-device model (CDM), per JEDEC specification JESD22-C101 <sup>(2)</sup>	±1000	

(1) JEDEC document JEP155 states that 500-V HBM allows safe manufacturing with a standard ESD control process.

(2) JEDEC document JEP157 states that 250-V CDM allows safe manufacturing with a standard ESD control process.

### 7.3 Recommended Operating Conditions

over operating free-air temperature range (unless otherwise noted)

		MIN	NOM	MAX	UNIT
+V <sub>CC</sub>	Positive supply voltage	4	6	7.9	V
–V <sub>CC</sub>	Negative supply voltage	–4	–6	–7.9	V
T <sub>A</sub>	Operating free-air temperature	–40	25	85	°C

### 7.4 Thermal Information

THERMAL METRIC <sup>(1)</sup>		THS3217	UNIT
		RGV (VQFN)	
		16 PINS	
R <sub>θJA</sub>	Junction-to-ambient thermal resistance	45	°C/W
R <sub>θJC(top)</sub>	Junction-to-case (top) thermal resistance	45	°C/W
R <sub>θJB</sub>	Junction-to-board thermal resistance	22	°C/W
Ψ <sub>JT</sub>	Junction-to-top characterization parameter	1	°C/W
Ψ <sub>JB</sub>	Junction-to-board characterization parameter	22	°C/W
R <sub>θJC(bot)</sub>	Junction-to-case (bottom) thermal resistance	4	°C/W

(1) Thermal impedance reported with backside thermal pad soldered to heat spreading plane. For more information about traditional and new thermal metrics, see the *Semiconductor and IC Package Thermal Metrics* application report, [SPRA953](#).

## 7.5 Electrical Characteristics: D2S

at  $V_{CC} = 6.0\text{ V}$ ,  $-V_{CC} = -6.0\text{ V}$ ,  $A_V = 2\text{ V/V}$ ,  $25\text{-}\Omega$  source impedance, input common-mode voltage ( $V_{IC}$ ) =  $0.25\text{ V}$ , external OPS input selected (PATHSEL  $\geq 1.3\text{ V}$ ),  $V_{REF} = \text{GND}$ ,  $R_{LOAD} = 100\text{ }\Omega$ , and  $T_J \approx 25^\circ\text{C}$  (unless otherwise noted)

PARAMETER	TEST CONDITIONS	MIN	TYP	MAX	UNIT	TEST LEVEL (1)

Input impedance differential mode	$V_{CM} = 0\text{ V}$		50    2.4		k $\Omega$    pF	C
Input impedance common mode	$V_{CM} = 0\text{ V}$		90    2.4		k $\Omega$    pF	C

(1) Test levels (all values set by characterization and simulation): (A) 100% tested at  $T_A \approx T_J \approx 25^\circ\text{C}$ ; over temperature limits by characterization and simulation. (B) Not tested in production; limits set by characterization and simulation. (C) Typical value only for information. DC limits tested with no self-heating. Add internal self heating to  $T_A$  for  $T_J$ .

(2) Output measured at pin 6.

(3) This slew rate is the average of the rising and falling time estimated from the large-signal bandwidth as:  $(V_{peak} / \sqrt{2}) \times 2\pi \times f_{-3dB}$ .

(4) Currents out of pin treated as a positive polarity.

(5) Applies to input pins 2 (IN+) and 3 (IN-).

## 8.2 Frequency Response Measurement

For D2S and full-signal path (D2S + OPS) characterization, the LMH3401, a very wideband, dc-coupled, single-ended to differential amplifier was used. The LMH3401EVM was used as an interface between a single-ended source and the differential input required by the D2S, shown in Figure 68. The LMH3401 provides an input impedance of 50  $\Omega$ , and converts a single-ended input to a differential output driving through 50- $\Omega$  outputs on each side to what is a 50- $\Omega$  termination at each input of the THS3217 D2S.

**Figure 68. Frequency-Response Measurement: D2S and Full-Path (D2S + OPS) Circuit Configurations**

The LMH3401 provides 7-GHz bandwidth with 0.1-dB flatness through 700 MHz. From the single-ended matched input (using active match through an internal 12.5- $\Omega$  resistor), the LMH3401 produces a differential output with 16-dB gain to the internal output pins. Building out to a 50- $\Omega$  source by adding external 40.2- $\Omega$  resistors on both differential outputs in series with the internal 10- $\Omega$  resistor, results in a net gain of 10 dB to the matched 50- $\Omega$  load on the THS3217EVM.

The maximum output swing test for the D2S stage is 4  $V_{PP}$  (see Figure 15 and Figure 16). With a fixed gain of 2 V/V, the tests in Figure 15 and Figure 16 require a 2- $V_{PP}$  differential input. In order to achieve the 2- $V_{PP}$  differential swing at the D2S inputs, the LMH3401 internal outputs must drive a 4- $V_{PP}$  differential signal around the  $V_{OCM}$  of the LMH3401. This LMH3401 single-to-differential preamplifier is normally operated with  $\pm 2.5$ -V supplies, and  $V_{OCM}$  set to ground. Under these conditions, the LMH3401 supports  $\pm 1.4$  V on each internal output pin; well beyond the maximum required for THS3217 D2S characterization of  $\pm 1$  V.

The output of the LMH3401EVM connects directly to the Vin+ (J1) and Vin- (J2) SMA connectors on the THS3217EVM, as shown in Figure 67. The physical spacing of the SMA connectors has been set to line up for a direct (no cabling) connection between the two different EVMs using SMA barrels. For THS3217 designs that must be evaluated before any DAC connection, consider using the LMH3401EVM as a gain of 10 dB, single-to-differential interface to the inputs of the D2S stage. This setup allows single-ended sources to generate differential output signals through the combined LMH3401EVM to THS3217EVM configuration. The D2S, small-signal, frequency-response curves over input common-mode voltage (see Figure 13) were generated by adjusting the LMH3401 voltage supplies and maintaining  $V_{OCM}$  at midsupply to preserve input headroom on the LMH3401. In order to make single-ended, frequency-response measurements, the configuration shown in Figure 69 was used.

**Figure 69. Frequency-Response Measurement: OPS Inverting and Noninverting, Midscale Buffer, and VREF Circuit Configurations**

### 8.3 Harmonic Distortion Measurement

The distortion plots for all stages used a filtered high-frequency function generator to generate a very low-distortion input signal. The LMH3401 interface was used when testing the D2S and the full-signal path (D2S+OPS) harmonic distortion performance. Running the filtered signal through the LMH3401, as shown in Figure 70, provided adequate input signal purity because of the approximately  $-100\text{-dBc}$  harmonic distortion performance through 100 MHz. In order to test the harmonic-distortion performance of the OPS and midscale buffer, the configuration shown in Figure 71 was used.

**Figure 70. Harmonic-Distortion Measurement: D2S and Full-Path (D2S + OPS) Circuit Configurations**

**Figure 71. Harmonic-Distortion Measurement: OPS Inverting and Noninverting and Midscale Buffer Circuit Configurations**

## 8.4 Noise Measurement

All the noise measurements were made using a very low-noise, high-gain bandwidth LMH6629 as a low-noise preamplifier to boost the output noise from the THS3217 before measurement on a spectrum analyzer, as shown in Figure 72. The 0.69-nV/√Hz input-voltage noise specification of the LMH6629 provides flat gain of 20 V/V through 100 MHz with its ultrahigh, 6.3-GHz gain bandwidth product. The D2S and OPS noise was measured with the common-mode voltage at GND.

Figure 72. Noise Measurement Using LMH6629 Preamplifier

## 8.5 Output Impedance Measurement

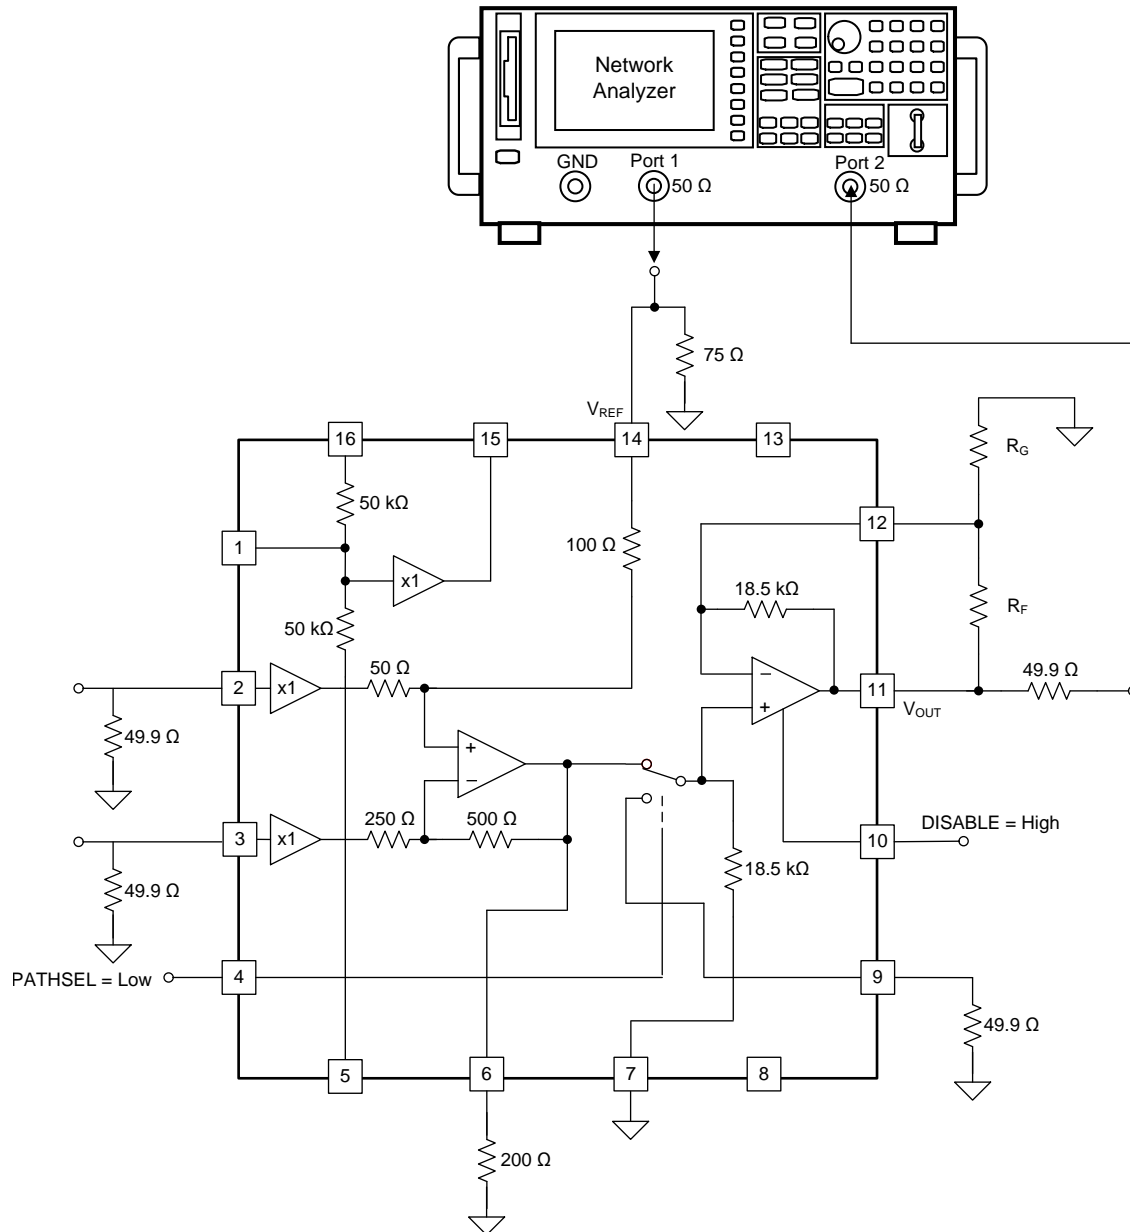

Output impedance measurement for the three stages under different conditions were performed as a small-signal measurement calibrated to the device pins using an impedance analyzer. Calibrating the measurement to the device pins removes the THS3217EVM parasitic resistance, inductance, and capacitance from the measured data.

## 8.6 Step-Response Measurement

Generating a clean, fast, differential-input step for time-domain testing presents a considerable challenge. A multichannel pulse generator with adjustable rise and fall times was used to generate the differential pulse to drive D2S inputs in Figure 21. A high-speed scope was used to digitize the pulse response.

## 8.7 Feedthrough Measurement

In order to test the forward feedthrough performance of the OPS in the disabled state, the circuit shown in Figure 73 was used. The PATHSEL pin was driven low to select the internal path between the D2S and OPS. A 100-mV<sub>PP</sub>, swept-frequency, sinusoidal signal was applied at the VREF pin and the output signal was measured at the OPS output pin (VOUT). The transfer function from VREF to the output of the D2S at VO1 has a gain of 0 dB, as shown in Figure 23. The results shown in Figure 57 account for the 6-dB loss due to the doubly-terminated OPS output, and therefore report the forward feedthrough between VOUT and VO1 at different OPS gains. The D2S inputs were grounded through 50-Ω resistors for this test.

**Figure 73. Forward-Feedthrough Test Circuit**

## Feedthrough Measurement (continued)

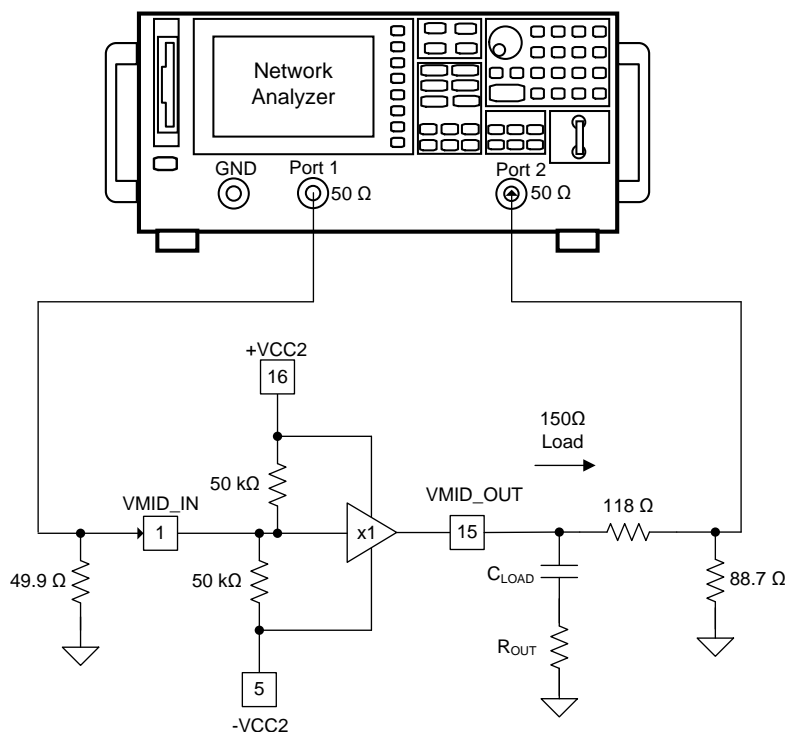

In order to test the reverse feedthrough performance of the OPS in its disabled state, the circuit shown in Figure 74 was used. The PATHSEL pin was driven high to select the external path to the OPS noninverting pin, VIN+. A 100-mV<sub>PP</sub>, swept-frequency, sinusoidal signal was applied at the VIN+ pin and the output signal was measured at the D2S output pin (VO1). The results shown in Figure 58 account for the 16.5-dB loss due to the D2S termination, and the test reports the reverse feedthrough between the VO1 and VIN+ pins. The D2S inputs were grounded through 50-Ω resistors for this test.

**Figure 74. Reverse-Feedthrough Test Circuit**

## 8.8 Midscale Buffer $R_{OUT}$ Versus $C_{LOAD}$ Measurement

For the tests in Figure 53 and Figure 54, the circuit shown in Figure 75 was used. The 150- $\Omega$  load circuit configured as shown, provides a 50- $\Omega$  path from the network analyzer back to the output of the buffer. As shown in Figure 75, place  $R_{OUT}$  below the load capacitor to improve the phase margin for the closed-loop buffer output, while adding 0- $\Omega$  dc impedance into the line connected to the VREF pin.

**Figure 75.  $R_S$  Versus  $C_{LOAD}$  Measurement Circuit**

## 9 Detailed Description

### 9.1 Overview

The THS3217 is a differential-input to single-ended output amplifier system that provides the necessary functional blocks to convert a differential output signal from a wideband DAC to a dc-coupled, single-ended, high-power output signal. The THS3217 typically operates using balanced, split supplies. Signal swings through the device can be adjusted around ground at several points within the device. Single-supply operation is also supported an ac-coupled signal path. The THS3217 supply voltage ranges from  $\pm 4.0$  V to  $\pm 7.9$  V. The two internal logic gates rely on a logic reference voltage at pin 7 that is usually tied to ground for any combination of power-supply voltages. The DISABLE control (pin 10) turns the output power stage (OPS) off to reduce power consumption when not in use.

A differential-to-single-ended stage (D2S) provides a high input impedance for a high-speed DAC (plus any reconstruction filter between the DAC and THS3217) operating over a common-mode input voltage range from  $-1$  V to  $+3.0$  V. This range is intended to support either current sourcing or current sinking DACs. The D2S is internally configured to reject the input common-mode voltage and convert the differential inputs to a single-ended output at a fixed gain of 2 V/V (6 dB).

An uncommitted, on-chip, wideband, unity-gain buffer is provided (between pins 1 and 15) to drive the VREF pin. The buffer offers extremely broad bandwidth to achieve very-low output impedance to high frequencies (Figure 51). The buffer does not provide a high full-power bandwidth because of a relatively low slew rate. The buffer stage includes a default midsupply bias resistor string of 50-k $\Omega$  each to set the default input to midsupply. This 25-k $\Omega$  Thevinin impedance is easily overridden with an external input source, but is intended to provide a midsupply bias for single-supply operation. The buffer amplifier that drives the VREF pin has two functions:

- Provides an easy-to-interface, dc-correction, servo-loop input
- Can be used as an offset injection point for the D2S output

The final OPS provides one of the highest-performance, current-feedback amplifiers available for line-driving applications. The 950-MHz SSBW stage provides 5000 V/ $\mu$ s of slew-rate, sufficient to drive a 5-V<sub>PP</sub> output with 500-MHz bandwidth. In addition, the OPS is able to drive a very-high continuous and peak output current sufficient to drive the most demanding loads at very high speeds. A unique feature added to the OPS is a 2  $\times$  1 input multiplexer at the noninverting input. The PATHSEL control (pin 4) is used to select the appropriate signal path to the OPS noninverting input. One of the multiplexer select paths passes the internal D2S output directly to the OPS. The other select path accepts an external input to the OPS at VIN+ (pin 9). This configuration allows the D2S output, available at VO1 (pin 6), to pass through an external RLC filter and back into the OPS at VIN+ (pin 9).

If the OPS does not require power for certain application configurations, a shutdown feature has been included to reduce power consumption. For designs that do not use the OPS at all, two internal fixed resistors are included to define the operating points for the disabled OPS. An approximate 18.5-k $\Omega$  resistor to the logic reference (pin 7) from VIN+ (pin 9), and an approximate 18.5-k $\Omega$ , fixed, internal feedback resistor are included to hold the OPS pin voltages in range if no external resistors are used around the OPS. These resistors must be included in the design calculations for any external network.

Two sets of power supply-pins have been provided for both the positive and negative supplies. Pin 5 (–VCC2) and pin 16 (+VCC2) power the D2S and midscale buffer stages, while pin 8 (–VCC1) and pin 13 (+VCC1) supply power to the OPS. The supply rails are connected internally by antiparallel diodes. Externally, connect power first to the OPS, then connect back on each side with a  $\pi$ -filter (ferrite bead + capacitor) to the input-stage supply pins (see Figure 90). Do not use mismatched supply voltages on either the positive or negative sides because the supplies are internally connected through the antiparallel diodes. Imbalanced positive and negative supplies are acceptable, however.

When the OPS is disabled, the output pin goes to high impedance. However, do not connect two OPS outputs from different devices together and select them as a *wired-or* multiplexer. Although the high-impedance output is disabled, the inverting node is still available through the feedback resistor, and can load the active signal. The signal path through the inverting node typically degrades the distortion on the desired active signal in a wired-or multiplexer configuration using CFA amplifiers.

## 9.2 Functional Block Diagram

### 9.3 Feature Description

### 9.3.1 Differential to Single-Ended Stage (D2S) With Fixed Gain of 2-V/V (Pins 2, 3, 6 and 14)

This buffered-amplifier stage isolates the DAC output nodes from the differential to single-ended conversion. Presenting two high-impedance inputs allows the DAC to operate in its best configuration independent of subsequent operations. The two very wideband input buffers hold an approximately constant response shape over a wide input common-mode operating voltage. [Figure 13](#) shows 6 dB of gain with 0.5-dB flatness through 500 MHz over the intended -1-to +3-V input common-mode range. In this case, the VREF pin is grounded, forcing the D2S output to be centered on ground for any input common-mode voltage. For the D2S-only tests, a 100- $\Omega$  load is used to showcase the performance of this stage directly driving a doubly-terminated cable. The wide input common-mode range of the D2S satisfies the required compliance voltage over a wide range of DAC types. Most current sourcing DACs require an average dc compliance voltage on their outputs near ground. Current sinking DACs require an average dc compliance voltage near their positive supply voltage for the analog section. The 3-V maximum common-mode range is intended to support DAC supplies up to 3.3 V, where the average output operating current pulls down from 3.3 V by the termination impedance from the supply. For instance, a 20-mA tail current DAC must level shift from a 3.3-V bias on the output resistors down to 3 V or lower. This DAC-to-THS3217 configuration requires at least a 300-mV dc level shift with half the tail current in each side, implying a 30- $\Omega$  load impedance to the supply on each side of the 20-mA reference current.

The overriding limits to the input common-mode operating range are due to the input buffer headroom. Over temperature, the D2S input headroom specification is 2 V to the negative supply and 1.5 V to the positive supply. Therefore, operation at a 3-V input common-mode voltage requires at least a 4.5-V positive supply, where 5 V is a more conservative minimum.

While DAC outputs rarely have any common-mode signal present (unless the reference current is being modulated), the D2S does a reasonable job of rejecting input common-mode signals over frequency. [Figure 17](#) shows the CMRR to decrease above 10 MHz. For current-sinking DACs coming from a positive supply voltage, any noise on the positive supply looks like an input common-mode signal. Keeping the noise small at higher frequencies reduces the possibility of feedthrough to the D2S output due to the decreasing CMRR at higher frequencies. A current-sinking DAC uses pull-up resistors to the voltage supply to convert the DAC output current to a voltage. Make sure that the DAC voltage supply has been properly decoupled through a ferrite bead and capacitor,  $\pi$ -filter network similar to the supply decoupling for the THS3217 shown in [Figure 90](#).

## Feature Description (continued)

The D2S provides a differential gain of 6 dB. The gain is reasonably precise using internal resistor matching with extremely low gain drift over temperature (see Figure 61 and Figure 62). The single-ended D2S output signal can be placed over a wide range of dc offset levels using the VREF pin. The VREF pin shows a precise gain of 1 V/V to the D2S output. Grounding VREF places the first stage output centered on ground (with some offset voltage). For best ac performance through the D2S, anything driving the VREF pin must have a very wide bandwidth with very low output impedance over frequency while driving a 150-Ω load. The on-chip midscale buffer provides these features (see Figure 51). When a dc offset (or other small-level ac signal) must be applied to the VREF pin, buffer the signal through the midscale buffer stage. Maintain the total range of the dc offset plus signal swing within the available output swing range of the D2S. The headroom to the supplies is a symmetric  $\pm 1.65$  V (max) over temperature. Therefore, on the minimum  $\pm 4$ -V supply, the D2S operates over a  $\pm 2.35$ -V output range. At the maximum  $\pm 7.9$ -V supply, a  $\pm 6.25$ -V output range is supported. At the higher swings, account for available linear output current, including the current into the internal feedback resistor load of approximately 500-Ω.

Figure 76 shows the internal structure of the D2S functional block. It consists of two internal stages:

1. The first stage consists of two wideband, closed-loop, fixed gain of 1 V/V buffers to isolate the requirements of the complementary DAC output from the difference operation of the D2S.
2. The second stage is a wideband CFA configured as a difference amplifier, operating in a fixed gain of 2 V/V, performing the differential to single-ended conversion.

Figure 76. D2S Operating Example

The CFA design offers the best, full-power bandwidth versus supply current, with moderate noise and dc precision. Figure 76 shows a typical current-sourcing DAC with a 20-mA total tail current. The tail current is split equally between the 25-Ω termination resistors to produce a dc common-mode voltage and a differential ac current signal. This example sets the input common-mode voltage at 0.25 V, and is also the compliance voltage of the DAC. The 25-Ω termination resistors shown here are typically realized as a 50-Ω matched reconstruction (or Nyquist) filter between the DAC and the THS3217 buffer inputs for most AWG applications. The DAC signal is further amplified by 6 dB in the second stage for a net transimpedance gain of 100-Ω to the D2S output at VO1. This configuration produces a 2-V<sub>PP</sub> output for the 20-mA reference current assumed in the example of Figure 76. The input common-mode voltage is cancelled on the two sides of the op amp circuit to give a ground referenced output. Any voltage applied to the VREF pin has a gain transfer function of 1 V/V to VO1, independent of the signal path, as long as the source impedance of VREF is very low at dc and over frequency.

## Feature Description (continued)

The IN+ buffer output drives a 150-Ω load with VREF grounded. Any source driving VREF must have the ability to drive a 150-Ω load with low output impedance across frequency. For differential input signals, the IN– buffer drives a 150-Ω active load. The active load is realized by a combination of the 250-Ω  $R_G$  resistor and the inverted and attenuated signal present at the inverting terminal of the difference amplifier stage. If only IN– is driven (with IN+ at a dc fixed level), the load is 250 Ω.

The resistor values around the D2S difference amplifier are derived in the following sequence, as shown in Figure 77:

1. Select the feedback resistor value to set the response shape for the wideband CFA stage. The 500-Ω design used here was chosen as a compromise between loading and noise constraints.
2. Set the input resistor on the inverting input side to give the desired single-sided gain for that path. Setting  $R_G = 250\text{-}\Omega$  results in a gain of  $-2\text{ V/V}$  from the buffered signal ( $-V$ ) to the output of the difference amplifier.
3. Solve the required attenuation to the noninverting input to get a matched gain magnitude for the signal provided at the buffer output ( $+V$ ) on the noninverting path. If  $\alpha = R_2 / (R_1 + R_2)$ , as shown in Figure 77, then the solution for  $\alpha$  is shown in Equation 2:

$$\alpha \left( 1 + \frac{R_F}{R_G} \right) = 2 \quad (1)$$

$$\alpha = \frac{2}{3} = \frac{R_2}{(R_1 + R_2)} \quad (2)$$

**Figure 77. D2S Impedance Analysis**

4. After solving the attenuation from the buffer output to the amplifier noninverting input, set the impedance ( $R_1 + R_2$ ). It is preferable to have the two first stage buffer outputs drive the same load impedance to match nonlinearity in their outputs in order to improve even-order harmonic distortion. The load impedance from  $-V$  to  $R_G$  has an active impedance because of the inverted and attenuated version of the input signal appearing at the inverting amplifier node from the  $+V$  input signal. Assuming a positive input signal into the  $+V$  path, an attenuated version of the signal appears at the amplifier summing junction side of  $R_G$ , while the inverted version of the signal appears on the input side of  $R_G$ .

The impedance seen at node  $-V$  in Figure 77 is derived in Equation 3 by solving for the  $V/I$  expression across  $R_G$ .

$$Z_i = \frac{R_G}{(1 + \alpha)} = \frac{250\ \Omega}{1 + \frac{2}{3}} = 150\ \Omega \quad (3)$$

For load balancing,  $(R_1 + R_2) = 150\ \Omega$  while the attenuation is  $\alpha$ . More generally, all the terms are now available to solve for  $R_2$ , as shown in Equation 4:

$$R_2 = R_G \frac{\alpha}{(\alpha + 1)} = 250\ \Omega \frac{\frac{2}{3}}{1 + \frac{2}{3}} = 100\ \Omega \quad (4)$$

$R_1$  is then simply  $(Z_i - R_2) = 50\ \Omega$ .

## Feature Description (continued)

This analysis for matched gains and buffer loads can be applied to a more general discrete design using different target gains and starting  $R_F$  values. It is clearly useful to have the attenuation and buffer loading accurately controlled. Therefore, it is very important to control the impedance at the VREF pin to be as low as possible. For instance, using the midscale buffer to drive the VREF pin only adds 0.21  $\Omega$  dc impedance in series with R2. This low dc output impedance can only be delivered with a closed-loop buffer design. For discrete implementations of this D2S, consider the [BUF602](#) buffer and [LMH6702](#) wideband CFA amplifier. For even better dc and ac output impedance in the buffers (and possibly better gain), use a closed-loop, dual, wideband op amp like the [OPA2889](#) for lower frequency applications, or the [OPA2822](#) for higher frequency. These unity gain stable op amps can be used as buffers offering different performance options along with the LMH6702 wideband CFA over the design point chosen for the THS3217.

After gain matching is achieved in the single op amp differential stage, the common-mode input voltage is cancelled to the output, and the VREF input voltage is amplified by 1 V/V to the output. The analysis circuit is shown in [Figure 78](#), where VREF is shown grounded at the R2 element.

**Figure 78. D2S Common-Mode Cancellation**

The gain magnitudes are equal on each side of the differential inputs; therefore, the common-mode inputs achieve the same gain magnitude, but opposite phase, resulting in common-mode signal cancellation. The inverting path gain is  $V_{CM} \times (R_F / R_G)$ . The noninverting path gain is  $V_{CM} \times \alpha \times (1 + R_F / R_G)$ . Using [Equation 5](#):

$$\alpha = \frac{\frac{R_F}{R_G}}{\left(1 + \frac{R_F}{R_G}\right)} \quad (5)$$

the noninverting path gain becomes  $+V_{CM} \times R_F / R_G$ , and adding that result to the inverting path signal cancels to zero. Slight gain mismatches reduce this rejection to the 55-dB typical CMRR, with a 47-dB tested minimum. The 47-dB minimum over the 3-V maximum common mode input range adds another  $\pm 13.4$ -mV worst-case D2S output offset term to the specified maximum  $\pm 35$ -mV output offset with 0-V input common-mode voltage. The polarity of the gain mismatch is random.

The VREF pin input voltage ( $V_{REF}$ ) generates a gain of 1 V/V using the analysis shown in [Figure 79](#)

**Figure 79. Gain Transfer Function from VREF to VO1**

## Feature Description (continued)

The gain from VREF to VO1 is shown in Equation 6:

$$V_{REF} \frac{R1}{(R1 + R2)} \left( 1 + \frac{R_F}{R_G} \right) = V_{O1} \quad (6)$$

Getting both R1 and (R1 + R2) in terms of R<sub>G</sub> and the target attenuation, α simplifies, as shown in Equation 7:

$$\frac{R1}{(R1 + R2)} = \frac{R_G \frac{1 - \alpha}{1 + \alpha}}{R_G \frac{1}{1 + \alpha}} = (1 - \alpha) \quad (7)$$

Putting Equation 7 back into the gain expression (Equation 6), and expanding out gives:

$$V_{REF} (1 - \alpha) \left( 1 + \frac{R_F}{R_G} \right) = V_{O1} \quad (8)$$

Recall that in order to get differential gain balance,  $\alpha = -(R_F / R_G)$ . Putting that into Equation 8 reduces the expression to  $V_{O1} = V_{REF}$ , a gain of 1 V/V. This gain is very precise as shown in the [D2S Electrical Characteristics](#) table, where the tested dc limits are 0.985 V/V to 1.015 V/V.

The D2S output offset and drift are largely determined by the internal elements. The only external consideration is the dc source impedance at the two buffer inputs. With low source impedance, the D2S output offset is tested to be within ±35 mV, that becomes a maximum ±17 mV input differential offset specification. Assuming the dc source impedances are closely matched, the mismatch in the two input bias currents adds another input offset term for higher source impedances. The input bias offset current is limited in test to be < ±0.40 μA. This error term does not rise to add more than ±1 mV input differential offset until the dc source impedance exceeds 2.5 kΩ. A high dc source impedance most commonly occurs in an input ac-coupled, single-supply application, where dc offsets are less critical.

The absolute input bias currents modifies the common-mode input voltage if the dc source resistance is too large. That term is tested to a limit of ±4 μA on each input. To move the input common mode voltage by ±100 mV, the dc source impedance must exceed 25 kΩ. This added input common-mode voltage is cancelled by the D2S at the output (VO1, pin6).

The D2S output noise is largely fixed by the internal elements. The D2S shows a differential input voltage noise of 9 nV/√Hz, and a current noise of 2 pA/√Hz on each input. Higher termination resistors increase this source noise, as given by Equation 9, where R<sub>t</sub> is the dc termination impedance at each buffer input. The D2S has a 1/f corner at approximately 30 kHz (see Figure 18).

$$e_{i\_diff} = \sqrt{(9nV)^2 + 2(4kTR_t) + 2(2pA \times R_t)^2} \quad (9)$$

The total differential input noise is dominated by the differential voltage noise. For instance, evaluating this expression for R<sub>t</sub> = 200 Ω on each input, increases the total differential input noise to 9.4 nV/√Hz, only slightly greater than the 9 nV/√Hz for the D2S with 0-Ω source R<sub>t</sub> on each input. If higher final output SNR is desired, consider generating as much input swing as the DAC can support, but increase the termination impedance. It is possible that a lower tail current with higher R<sub>t</sub> will yield improved SNR at the D2S input. This differential input noise appears at the D2S output times a gain of 2 V/V.

$$e_{out\_diff} = 2 \times e_{i\_diff} \quad (10)$$

### 9.3.2 Midscale (DC) Reference Buffer (Pin 1 and Pin 15)

This optional block can be completely unconnected and not used if the design does not require this feature. Internal 50-kΩ resistors to the power supplies bias the input of the buffer to the midpoint of the supplies used. The internal resistors set a midsupply operating point when the buffer is not used, as well as a default midsupply point at the buffer output to be used in other stages for single-supply, ac-coupled applications.

## Feature Description (continued)

The buffer provides a very wideband, low output-impedance when used to drive the VREF pin (see Figure 51). To provide this low broadband impedance, the closed-loop midscale (dc) reference buffer offers a very broadband SSBW, but only a modest large-signal bandwidth (LSBW); see Figure 49. This path is not normally intended to inject a wideband signal, but can be used for lower-amplitude signals. Driving the buffer output into the VREF pin allows a wideband small-signal term to be added into the D2S along with the signal from the differential inputs.

The midscale (or dc) reference buffer injects an offset voltage to the output offset of the D2S when it drives the VREF pin. The offset has very low drift, but consider the effect of the input bias current times the dc source impedance at VMID\_IN (pin 1). When used as a default midsupply reference for single-supply operation, the input to this buffer is just the average of the total power supplies through a 25-k $\Omega$  source impedance. Add an external capacitor to filter the supply and the 50-k $\Omega$  internal resistors. A 1- $\mu$ F capacitor on pin 1 adds a 6-Hz pole to the noise sources. If lower noise at lower frequencies is required, implement a midscale divider with external, lower-valued resistors in parallel with the internal 50-k $\Omega$  values.

If the midscale buffer drive the VREF pin, another noise term is added to Equation 9 and Equation 10. The midscale buffer 4.4-nV/ $\sqrt{\text{Hz}}$  voltage noise is amplified by 0 dB, and adds (RMS) a negligible impact to the total D2S output noise. The biggest impact comes when the internal default 50-k $\Omega$  dividers are used. Be sure to decouple pin 1 with at least a 1- $\mu$ F capacitor in the application to reduce the noise contribution through this path. Figure 80 is the simulation circuit where the only change is to add or remove the 1- $\mu$ F capacitor.

Figure 80. Midscale Buffer Noise Model

Figure 81 shows the simulated output noise for the midscale buffer using the internal 50-k $\Omega$  divider with and without a 1- $\mu$ F capacitor on pin 1.

Figure 81. Buffer-Output Noise Comparison With and Without the 1- $\mu$ F Bypass Capacitor on Pin 1

## Feature Description (continued)

In the flat region, the 1- $\mu$ F capacitor reduces the midscale buffer output spot noise from approximately 55 nV/ $\sqrt{\text{Hz}}$  to 4.4 nV/ $\sqrt{\text{Hz}}$ . If the noise below 100 Hz is unacceptable, either add a low-noise buffer to drive this input, or add lower-value resistors externally to set up the midsupply bias. Also, consider the noise impact of any reference voltage source driving the midscale buffer path.

### 9.3.3 Output Power Stage (OPS) (Pins 4, 7, 9, 10, 11, and 12)

This wideband current-feedback amplifier (CFA) provides a flexible output driver with several unique features. The OPS can be left unused if the specific application only uses the D2S alone, or a combination of the D2S with an off-chip power driver. If left unused, simply tie DISABLE (pin 10) and PATHSEL (pin 4) to the positive supply. This logic configuration turns the OPS off and opens up the external and internal OPS noninverting input paths. An internal fixed 18.5-k $\Omega$  resistor holds the external input pin at the logic reference voltage on pin 7. Additionally, the OPS output is connected to the inverting input through another internal 18.5-k $\Omega$  resistor when no external resistors are installed on pins 9, 11, or 12. Disabling the OPS saves approximately 21 mA of supply current from the nominal total 54 mA with all stages operating on  $\pm 6$ -V supplies.

The noninverting input to the OPS provides two possible paths controlled by the PATHSEL logic control, pin 4. With the logic reference (pin 7) at ground, floating pin 4 or controlling it to a voltage < 0.7 V connects the input path directly to the internal D2S output. Tying pin 4 to the positive supply, or controlling it to a logic level > 1.3 V, connects the input path to the external input at pin 9. The intent for this switched input is to allow an external filter to be inserted between the D2S output and OPS inputs when needed, and bypass the filter when not. Alternatively, this switched input also allows a completely different signal path to be inserted at the OPS input, independent of that available at the internal D2S output.

In situations where the D2S output at pin 6 is switched into another off-chip power driver, the OPS can be disabled using pin 10. With the logic reference (pin 7) at ground, floating pin 10, or controlling it to a voltage < 0.7 V, enables the OPS. Tying pin 10 to the positive supply, or controlling it to a logic level > 1.3 V, disables the OPS.

Operation of the wideband, current-feedback OPS requires an external feedback resistor and a gain element. After configuring, the OPS can amplify the D2S output through either the noninverting path, or be configured as an inverting amplifier stage using the external OPS input at pin 9 as a dc reference.

One of the first considerations when designing with the OPS is determining the external resistor values as a function of gain in order to hold the best ac performance. The loop gain (LG) of a CFA is set by the internal open-loop transimpedance gain from the inverting error current to the output, and the effective feedback impedance to the inverting input. The nominal internal open-loop transimpedance gain and phase are shown in Figure 82.

**Figure 82. Simulated OPS  $Z_{OL}$  Gain And Phase**

## Feature Description (continued)

The feedback transimpedance ( $Z_{OPT}$ ) can be approximated as shown in Equation 11, where  $R_i$  is the open-loop, high-frequency impedance into the inverting node of the OPS. For a detailed derivation of Equation 11, see *Setting Resistor Values to Optimize Bandwidth* section in the OPA695 datasheet (SBOS293).

$$Z_{OPT} \approx R_F + \left(1 + \frac{R_F}{R_G}\right) R_i \quad (11)$$

As the signal gain is varied, hold  $Z_{OPT}$  approximately constant to hold the ac response constant over gain. Holding  $Z_{OPT}$  constant is a requirement to solve for  $R_F$ . An example of the THS3217 OPS  $R_F$  derivation is shown in Equation 12:

$$R_F = 351 \, \Omega - \left(1 + \frac{R_F}{R_G}\right) \times 42 \, \Omega \quad (12)$$

The calculations are complicated by the internal feedback resistor value of approximately 18.5-k $\Omega$ . After the external  $R_F$  is approximately set by the constant bandwidth consideration, the  $R_G$  must be set considering the other gain error terms. From the noninverting input of a CFA op amp, the total gain to the output includes a loss through the input buffer stage (described by the CMRR) and the loop gain (LG) loss set by the typical dc open-loop transimpedance gain and the feedback transimpedance. Extract the buffer gain from the VIN+ input to the VIN– input from the CMRR using Equation 13. This gain loss only applies to the noninverting mode of operation and can be neglected in inverting mode operation.

$$\beta = \left(1 - 10^{\frac{-CMRR}{20}}\right) = \text{Buffer Gain CFA} \quad (13)$$

The OPS has a typical CMRR of 49 dB (buffer gain,  $\beta = 0.9965$ ) with a tested minimum of 47 dB (minimum buffer gain of 0.9955). The dc LG adds to the gain error. The LG is given by Equation 14 where the typical design gain of 2.5 V/V value is also shown (the 245  $\Omega$  shown for  $R_F$  is the external 249- $\Omega$  feedback resistor in parallel with the internal 18.5-k $\Omega$  feedback resistor).

$$LG = \frac{Z_{OL}}{(R_F + NG \times R_i)} = \frac{1 \, M\Omega}{(245 \, \Omega + 2.5 \times 42 \, \Omega)} = 2857 \quad (14)$$

The closed-loop output impedance with a heavy load also adds a minor gain loss that is neglected here. The total noninverting gain is then set by Equation 15 (remember to include the internal  $R_F$  in this analysis. The  $R_F$  shown here is the parallel combination of the internal and external feedback resistors).

$$A_v^+ = \beta \times \left(1 + \frac{R_F}{R_G}\right) \times \frac{LG}{(1 + LG)} \quad (15)$$

Using nominal values for each term at the specified  $R_F = 249 \, \Omega$  and  $R_G = 162 \, \Omega$  gives the gain calculation in Equation 16, yielding a nominal gain very close to 2.5 V/V.

$$A_v^+ = 0.9965 \times \left(1 + \frac{245.7}{162}\right) \times \frac{2857}{1 + 2857} = 2.507 \quad (16)$$

Testing the total gain spread with the internal variation in buffer gain, open-loop transimpedance gain, internal feedback resistor, and  $\pm 1\%$  external resistor variation gives a worst-case gain spread of 2.49 V/V to 2.51 V/V. The gain error is primarily dominated by the external 1% resistors. For the tighter tolerance shown in Table 2, use 0.1% precision resistors.

## Feature Description (continued)

At very low gains ( $< 1.5$  V/V) parasitic LC effects at the inverting input render a flat frequency response impossible. Looking then at gains from 1.5 V/V and up, a table of nominally recommended  $R_F$  and  $R_G$  values is shown in [Table 2](#). Do not operate the OPS in noninverting gains of less than 2.5 V/V for large output signals because the limited slew-rate of the CFA input buffer causes signal degradation. [Table 2](#) accounts for the nominal gain losses described previously, and uses standardized resistor values to minimize the nominal gain-error to target gain. The calculation also restricts the solution to a minimum  $R_G = 20\ \Omega$ . The gain calculations include the nominal buffer gain loss, the loop-gain effect, and the nominal internal feedback resistor = 18.5 k $\Omega$ .

**Table 2. Optimized  $R_F$  Values for Different OPS Noninverting Signal Gains**

TARGET GAIN (V/V)	MEASURED SSBW (MHz)	BEST $R_F$ ( $\Omega$ )	BEST $R_G$ ( $\Omega$ )	CALCULATED GAIN		GAIN ERROR (%)

The measured bandwidths in [Table 2](#) come from [Figure 25](#) using the resistor values in the table and a 100- $\Omega$  load. Plotting the  $R_F$  value versus gain gives the curve of [Figure 83](#). The curve shows some ripple due to the standard value resistors used to minimize the target dc gain error.

**Figure 83. Suggested External  $R_F$  Value vs Noninverting Gain for the OPS**

Using  $R_F$  values greater than the recommended values in Table 2 band-limits the response, whereas using less than the recommended  $R_F$  values peaks the response. Using the values shown in Table 2 results in an approximately constant SSBW (see Figure 25). Holding a more constant loop-gain over the external gain setting also acts to hold a more constant output impedance profile, as shown in Figure 84. The swept-frequency, closed-loop, output impedance is shown for gains of 2.5 V/V, 5 V/V, and 10 V/V using the  $R_F$  and  $R_G$  values of Table 2. The first two steps do a good job of delivering the same (and very low) output impedance over frequency, while the gain of 10 V/V shows the expected higher closed-loop output impedance due to the reduced loop-gain and bandwidth.

**Figure 84. OPS Closed-Loop Output Impedance vs Gain Setting**

Reducing the  $R_F$  value with increasing gain also helps minimize output noise versus a fixed  $R_F$  design. See Figure 39 for the three noise terms for the OPS. The total output noise calculation is shown in Equation 17:

$$e_o = \sqrt{\left(e_{ni}^2 + 4kTR_S + (i_{bn}R_S)^2\right)NG^2 + (i_{bi}R_F)^2 + (4kTR_F)NG}$$

where

- $R_S$  is the source impedance on the noninverting input. If the OPS is driven from the D2S stage directly using the internal path,  $R_S \approx 0 \Omega$ .
- $NG = (1 + R_F / R_G)$  for the design point.
- The flat-band noise numbers for the OPS are:
  - $E_{ni} = 3.2 \text{ nV}/\sqrt{\text{Hz}}$
  - $I_{bn} = 2.7 \text{ pA}/\sqrt{\text{Hz}}$
  - $I_{bi} = 30 \text{ pA}/\sqrt{\text{Hz}}$

(17)

Using the values of  $R_F$  and  $R_G$  listed in Table 2, a swept gain output- and input-referred noise estimate is computed, as shown in Table 3. In this sweep,  $R_S = 0 \Omega$ . The input-referred noise ( $E_{ni}$ ) in Table 2 is at the noninverting input of the OPS. To refer the noise to the D2S differential inputs, divide the output noise by two if there is no interstage loss. Dividing the  $E_{ni}$  column by 2 V/V shows that the OPS noise contribution is negligible when referred to the D2S inputs, where the 9-nV/ $\sqrt{\text{Hz}}$  differential input noise dominates. Operating with higher feedback resistors in the OPS quickly increases the output noise due to the inverting input current noise term. Although increasing  $R_F$  improves phase margin (for example, when driving a capacitive load), be careful to check the total output noise using Equation 17.

**Table 3. Total Input- and Output-Referred Noise of the OPS Versus Gain**

TARGET GAIN (V/V)	BEST $R_F$ ( $\Omega$ )	BEST $R_G$ ( $\Omega$ )	$E_{o\_}$ (nV/ $\sqrt{\text{Hz}}$ )	$E_{in\_}$ (nV/ $\sqrt{\text{Hz}}$ )

10	187	20.5	33.6	3.4

Operating the OPS as an inverting amplifier is also possible. When driving the OPS directly from the D2S to the  $R_G$  resistor, use the values shown in Table 2 for the noninverting mode to achieve good results. Note that the  $R_G$  resistor is the load for the D2S stage. Operating with the D2S driving an  $R_G < 80 \Omega$  increases the harmonic distortion of the D2S. In that case, scaling  $R_F$  and  $R_G$  up to reduce the loading may result in better system performance at the cost of a lower OPS bandwidth. Driving the D2S output at pin 6 into the OPS in an inverting mode allows for the option to select the external input of the OPS, and drive another signal or dc level into the noninverting input at pin 9. In order to reduce layout parasitics, consider splitting the  $R_G$  resistor in two, with the first half close to pin 6 and the second half close to pin 12. Splitting  $R_G$  in this manner places the trace capacitance inside the two resistors keeping both active nodes more stable. Also, open up the ground and power planes under the trace, if possible.

Using the PS to receive and amplify a signal in the inverting mode with a matched terminating impedance, requires another resistor to ground ( $R_M$ ) along with  $R_G$ . This  $R_M$  resistor is shown in Figure 85 for a 50- $\Omega$  matched input impedance design.

**Figure 85. Inverting OPS Operation With Matched Input Impedance**

Table 4 gives the recommended external resistor values versus gain for the inverting gain mode with input matching configuration. Table 4 solves for the required  $R_F$  to simultaneously allow the gain, input impedance (50  $\Omega$ ), and feedback transimpedance to be controlled to the optimum target values. The table includes the effect of the internal 18.5-k $\Omega$  feedback resistor, and minimizes the RMS error to input impedance target ( $Z_i$ ) and overall gain.

**Table 4. Resistor Values Versus Gain for the Inverting OPS Configuration**

TARGET GAIN (V/V)	MEASURED SSBW (MHz)	BEST $R_F$ ( $\Omega$ )	BEST $R_G$ ( $\Omega$ )	BEST $R_M$ ( $\Omega$ )	CALCULATED GAIN		GAIN ERROR (%)	$Z_i$ ( $\Omega$ )	$Z_i$ ERROR (%)

10	260	499	49.9	Open	9.990	19.991	-0.100	49.90	-0.200

At higher gains,  $R_M$  increases to larger values, and the resistor is excluded from the circuit. The resulting input impedance of the network is resistor  $R_G$ . From that point,  $R_F$  simply increases to get higher gains, thereby rapidly reducing the SSBW. However, below a gain of -5 V/V, the inverting design with the values shown in Table 4 holds a more constant SSBW versus the noninverting mode (see Figure 26).

### 9.3.3.1 Output DC Offset and Drift for the OPS

The OPS provides modest dc precision with typical and maximum dc error terms in [Table 5](#). The input offset voltage applies to either input path with very little difference between the internal and external paths.

**Table 5. Typical Offset and Bias Current Values for the OPS**

PARAMETER	TYPICAL	MINIMUM	MAXIMUM	UNIT
$V_{IO}$	$\pm 1$	-12	12	mV
$I_{bn}$	5	-5	15	$\mu A$
$I_{bi}$	$\pm 5$	-40	40	$\mu A$

Selecting the internal path results in no source resistance for  $I_{bn}$ , so that term drops out. When the external path is selected, a dc source impedance may be present, so the  $I_{bn}$  term creates another error term, and adds to the total output offset.

Stepping through an example design for the OPS output dc offset using the external path with a low insertion loss filter shown in [Figure 92](#), along with its  $R_F$  and  $R_G$  values, gives the following results:

- $R_S$  for the  $I_{bn}$  term =  $34\ \Omega \parallel 249\ \Omega = 30\ \Omega$ . (dc source impedance for the filter design)
- $R_F$  including the internal  $18.5\ k\Omega$  resistor =  $249\ \Omega \parallel 18.5\ k\Omega = 245.7\ \Omega$
- Resulting gain with the  $130\text{-}\Omega$   $R_G$  element =  $2.89\ V/V$

[Table 6](#) shows the typical and worst-case output error terms. Note that a positive current out of the noninverting input gives a positive output offset term, whereas a positive current out of the inverting input gives a negative output term.

**Table 6. Output Offset Voltage Contribution From Various Error Terms at 25°C**

ERROR TERM	TYPICAL	MINIMUM	MAXIMUM	UNIT
$I_{bn} \times R_S \times A_V$	0.433	-0.43	1.29	mV
$V_{IO} \times A_V$	$\pm 2.89$	-34.68	34.68	mV
$I_{bi} \times R_F$	$\pm 1.22$	-9.83	9.83	mV
Total error	-3.67 to +4.54	-44.94	45.8	mV

The input offset voltage dominates the error terms. The worst-case numbers are calculated by adding the individual errors algebraically, but is rarely seen in practice. None of the OPS input dc error terms are correlated. To compute output drift numbers, use the same gains shown in [Table 6](#) with the specified drift numbers.

The OPS PATHSEL control responds extremely quickly with low-switching glitches, as shown in [Figure 86](#). For this test, the D2S input is set to GND, and the output of the D2S is connected to the external OPS input. The PATHSEL switch is then toggled at 10 MHz. The results show the offset between the internal and external paths as well matched.

**Figure 86. OPS Path-Select Switching Glitch**

The OPS includes a disable feature that reduces power consumption from approximately 21 mA to 2.4 mA. The logic controls are intended to be ground-referenced regardless of the power supplies used. The logic reference (GND, pin 7) is normally grounded and also provides a connection to the internal 18.5-k $\Omega$  resistor on pin 9 (default bias to pin 7). Operating in a single-supply configuration with  $-V_{CC}$  at GND and the external OPS input (pin 9) floated, places pin 9 internally at  $-V_{CC} = \text{GND}$ . Driving the external OPS input (pin 9) from a source within the operating range overrides the bias to  $-V_{CC}$ . However, if the application requires pin 9 to be floated in a single-supply operation, consider centering the voltage on pin 9 with an added 18.5-k $\Omega$  external resistor to the  $+V_{CC}$  supply.

If the disable feature is not needed, simply float or ground DISABLE (pin 10) to hold the OPS in the enabled state. Increasing the voltage on the DISABLE pin greater than 1.3 V disables the OPS and reduces the current to approximately 2.4 mA. If the OPS is unused in the application, it can be disabled by tying pin 10 to  $+V_{CC}$ , even up to the maximum operating supply of 15.8 V in a single-supply design.

Do not move the logic threshold away from those set by the logic ground at pin 7. If a different logic swing level is required, and pin 7 is biased to a different voltage, be sure the source can sink the typical 280  $\mu\text{A}$  coming out of pin 7. Also recognize that the 18.5-k $\Omega$  bias resistor on the external OPS input (pin 9) is connected to pin 7 voltage internally.

As shown in Figure 56, the OPS enables in approximately 100 ns from the logic threshold at 1.0 V while disabling to a final value in approximately 500 ns.

### 9.3.3.2 OPS Harmonic Distortion (HD) Performance

The OPS in the THS3217 provides one of the best HD solutions available through high power levels and frequencies. Figure 31 and Figure 32 show the swept-frequency HD2 and HD3, where the second harmonic is clearly the dominant term over the third harmonic. Typical wideband CFA distortion is reported only through 2- $V_{PP}$  output while Figure 31 and Figure 32 provide sweeps at 5  $V_{PP}$  and 8  $V_{PP}$  into a 100- $\Omega$  load. These curves normally show a 20-dB per decade rise with frequency due to loop-gain roll-off. At the highest 8- $V_{PP}$  swing, the onset of slew rate limited HD is seen at approximately 40 MHz. The required output signal slew rate at 8  $V_{PP}$  and 40 MHz is  $4 V_{PEAK} \times 2\pi \times 40 \text{ MHz} = 1000 \text{ V}/\mu\text{s}$ . The output signal requires 1/5 of the available slew rate that will take the HD2 off the 20-dB per decade rate in the  $-50\text{-dBc}$  operating region shown. A slight shift in the HD3 slope is also seen around 40 MHz for 8- $V_{PP}$  output in Figure 32.

The distortion performance is extremely robust as a function of  $R_{LOAD}$  (see Figure 33 and Figure 34). Normally, heavier loads degrade the distortion performance, as seen for the HD3 in Figure 34. However, the HD2 actually improves slightly going from a 200- $\Omega$  load to a 100- $\Omega$  load.

One of the key advantages offered by the CFA design in the OPS is that the distortion performance holds approximately constant over gain, as seen in the full-path distortion measurements of Figure 7 and Figure 8. Here, the D2S provides a fixed gain of 2 V/V driving a 200- $\Omega$  interstage load and using the internal path to drive the OPS at gains from 1.5 V/V to 10 V/V. Holding the loop-gain approximately constant by adjusting the feedback  $R_F$  value with gain results in vastly improved performance versus a voltage-feedback-based design.

Testing a 5- $V_{PP}$  output from the OPS with the supplies swept from the minimum  $\pm 4 \text{ V}$  to  $\pm 7.5 \text{ V}$  in Figure 35 and Figure 36 show:

1. The 1.5-V headroom on  $\pm 4\text{-V}$  supplies and  $\pm 2.5\text{-V}$  output voltage results in degraded performance. At the lower supplies, target lower output swings for improved linearity performance.
2. The HD2 does not change significantly with supply voltages above  $\pm 5 \text{ V}$ . The HD3 does improve slightly at higher supply-voltage settings.

From these plots at  $\pm 7.5\text{-V}$  supplies, a 5- $V_{PP}$  output into 100- $\Omega$  load shows better than  $-60\text{-dBc}$  HD2 and HD3 performance through 50 MHz. This exceptional performance is available with the OPS configured as a standalone amplifier. Combining this performance with the D2S stage (see Figure 3 and Figure 4) degrades the distortion due to the D2S and OPS harmonics combining in phase, and internal coupling between the stages. With the D2S and OPS running together at a final 5- $V_{PP}$  output and 50 MHz, the HD2 drops to  $-50 \text{ dBc}$ , and HD3 to  $-58 \text{ dBc}$  on  $\pm 6\text{-V}$  supplies. Lower output swings for the combined stages provide much lower distortion. The 2- $V_{PP}$  output curves on Figure 3 and Figure 4 show  $-57 \text{ dBc}$  for HD2, and a remarkable  $-76 \text{ dBc}$  for HD3 at 50 MHz.

### 9.3.3.3 Switch Feedthrough to the OPS

The OPS has two logic control pins, giving four combinations of states; therefore, various feedthrough effects must be considered. Figure 57 and Figure 58 show the feedthrough of the switches with the OPS disabled. With the OPS enabled, the signal feedthrough from the deselected input to the OPS output is shown in Figure 87 and Figure 88 at different closed-loop OPS gains. The results are shown for a 100-mV<sub>PP</sub> signal at the deselected input and are not normalized to the gain of the OPS. Adding a low-pass filter between the DAC and the D2S inputs helps reduce the feedthrough at higher frequencies.

**Figure 87. Forward Feedthrough With OPS Enabled, Internal Path Selected**

**Figure 88. Forward Feedthrough With OPS Enabled, External Path Selected**

### 9.3.3.4 Driving Capacitive Loads

The OPS can drive heavy capacitive loads very well as shown in [Figure 43](#) to [Figure 48](#). All high-speed amplifiers benefit from the addition of an external series resistor to isolate the load capacitor from the feedback loop. Not having the series isolation resistor often leads to response peaking and possibly oscillation. If frequency response flatness under capacitive load is the design goal, all CFA type amplifiers benefit by operating with slightly higher  $R_F$  values. Targeting a slightly higher feedback transimpedance increases the nominal phase margin before the capacitive load acts to decrease it. Using a higher  $R_F$  value has the effect of achieving good flatness across a range of capacitive loads using lower external series resistor values. Although the suggested  $R_F$  and  $R_G$  values of [Table 7](#) apply when driving a 100- $\Omega$  load, if the intended load is capacitive (for example, a passive filter with a shunt capacitor as the first element, another amplifier, or a Piezo element), use the values reported in [Table 7](#) as a starting point. The values in [Table 7](#) were used to generate [Figure 43](#) and [Figure 44](#). The results come from a nominal total feedback transimpedance target of 405  $\Omega$  (versus 351  $\Omega$  used for [Table 4](#)), and includes the internal 18.5-k $\Omega$  resistor in the design. [Table 7](#) finds the least error to target gain in the selection of standard resistor values, and limits the minimum  $R_G$  to 20  $\Omega$ . The gains calculated here put 18.5-k $\Omega$  in parallel with the reported external standard value  $R_F$ .

**Table 7. Suggested  $R_F$  and  $R_G$  Over Gain When Driving a Capacitive Load**

TARGET GAIN (V/V)	BEST $R_F$ ( $\Omega$ )	BEST $R_G$ ( $\Omega$ )	CALCULATED GAIN		GAIN ERROR (%)
			(V/V)	(dB)	
1.5	348	681	1.501	3.529	0.077
2	332	324	2.011	6.070	0.575

As the capacitive load or amplifier gain increases, lower series resistor values can be used to hold a flat response (see [Figure 43](#)). See [Figure 44](#) for the measured SSBW shapes for various capacitive loads configured with the suggested series resistor from the output of the OPS and the  $R_F$  and  $R_G$  values suggested in [Table 7](#) for a gain of 2.5 V/V. This measurement includes a 200- $\Omega$  shunt resistor in parallel with the capacitive load as a measurement path.

[Figure 45](#) and [Figure 46](#) demonstrate the OPS harmonic distortion performance when driving a range of capacitive loads. These show suitable performance for large-signal, piezo-driver applications. If voltage swings higher than 12  $V_{PP}$  are required, consider driving the OPS output into a step-up transformer. The high peak-output current for the OPS supports very fast charging edge rates into heavy capacitive loads, as shown in the step response plots (see [Figure 47](#) and [Figure 48](#)). This peak current occurs near the center of the transition time driving a capacitive load. Therefore, the  $I \times R$  drop to the capacitive load through the series resistor is at a maximum at midtransition, and back to zero at the extremes (low  $dV/dT$  points).

### 9.3.4 Digital Control Lines

The THS3217 provides two logic input lines that provide control over the input path to the OPS and the OPS power disable feature; both are referenced to GND (pin 7). The control logic defaults to a logic-low state when the pins are externally floated. Pin 7 must have a dc path to some reference voltage for correct operation. Float the two logic control lines to enable the OPS and select the internal path connecting the D2S internal output to the OPS noninverting input. Figure 89 shows a simplified internal schematic for either logic control input pin.

**Figure 89. Logic Control Internal Schematic**

The Q2 branch of the differential pair sets up a switch threshold approximately 1 V greater than the voltage applied to pin 7 (GND). If the control input is floating or  $< 0.7$  V, the differential-pair tail current diverts to the 100-Ω detector load, and results in an output voltage ( $V_{CTRL}$ , shown in Figure 89) that activates the desired mode. The floated pin default voltage is the PNP base current into the 19-kΩ resistor. As the control pin voltage rises above 1.3 V, the differential-pair current is completely diverted away from the 100 Ω side, thus switching states.

This unique design allows the logic control inputs to be connected to a single-supply as high as 15.9 V, in order to hold the inputs permanently high, while still accepting a low ground-referenced logic swing for single-supply operation. The NPN transistor (Q3) and two diodes (D1 and D2) act as a clamp to prevent large voltages from appearing across the differential stage.

When the OPS is disabled, both input paths to the OPS are also opened up regardless of the state of PATHSEL (pin 4).

## 9.4 Device Functional Modes

Any combination of the three internal blocks can be used separately, or in various combinations. The following sections describe the various functional modes of the THS3217.

### 9.4.1 Full-Signal Path Mode

The full-signal path from the D2S to the OPS is available in various options. Three options are described in the following subsections.

#### 9.4.1.1 Internal Connection With Fixed Common-Mode Output Voltage

The most basic operation is to ground the VREF pin, and use the internal connection from the D2S to the OPS to provide a differential to single-ended, high-power driver. Figure 90 shows the characterization circuit used for the combined performance specifications.

## Device Functional Modes (continued)

**Figure 90. Differential to Single-Ended, Gain of 5-V/V Configuration**

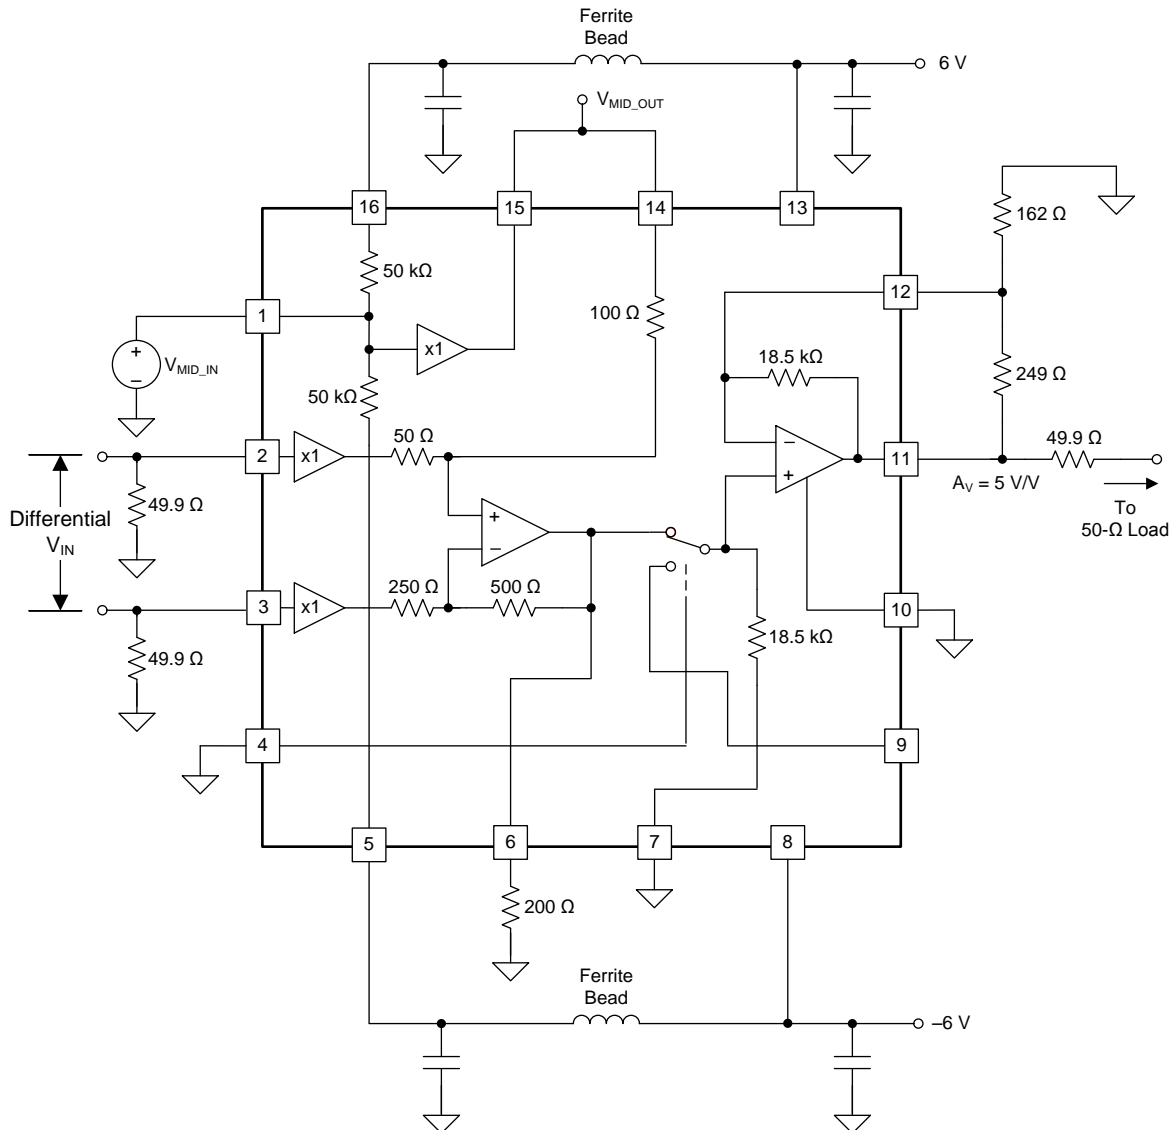

This configuration shows the test circuit used to generate [Figure 1](#). Some of the key features in this basic configuration include:

1. The power supplies are brought into the OPS first, then back to the input stage through a  $\pi$ -filter comprised of a ferrite bead and local decoupling caps on  $-VCC2$  and  $+VCC2$ , pins 5 and 16, respectively (see the [Power Supply Recommendations](#) section for more information).
2. The two logic lines are grounded. This logic configuration (with pin 7 grounded) selects the internal path from the D2S to OPS, and enables the OPS.
3. The external I/O pins of the midscale buffer are left floating.
4. The VREF pin is grounded, thus setting the D2S output common-mode voltage at VO1 (pin 6) to ground.
5. The D2S external output is loaded with a 200- $\Omega$  resistor to ground. Lighter loading on the VO1 pin (versus the 100  $\Omega$  used to characterize the D2S only) results in increased frequency response peaking. Heavier loading degrades the D2S distortion performance.
6. The external OPS input at pin 9 is left floating. However, it is internally tied to ground by the internal 18.5-k $\Omega$  resistor.
7. The feedback resistor in the OPS is set to the parallel combination of the external 249- $\Omega$  resistor and the internal 18.5-k $\Omega$  resistor. This 245.7- $\Omega$  total  $R_F$  with the 162- $\Omega$   $R_G$  resistor gives a gain of approximately 2.5 V/V (7.98 dB) in the OPS stage
8. The input D2S gives a gain of 2 V/V (6 dB), and along with the 2.5 V/V (7.98 dB) from the OPS, gives an overall gain of 5 V/V (13.98 dB) with > 700 MHz of SSBW (see [Figure 1](#)).

## Device Functional Modes (continued)

### 9.4.1.2 Internal Connection With Adjustable Common-Mode Output Voltage

The simplest modification to this starting configuration is using the midscale buffer to drive the VREF pin with either a dc or ac source into VMID\_IN (pin 1), shown in [Figure 91](#).

**Figure 91. Differential to Single-Ended, Gain of 5-V/V Configuration With VREF Driven by the Midscale Buffer**

The VREF input can be used to offset the output of the D2S that will then be amplified by the OPS. The total dc offset at the output of the OPS can also be corrected by adjusting the voltage at VMID\_IN (pin 1). The on-chip midscale buffer can be used as a low-impedance source to drive the correction voltage to the VREF pin. A wideband small-signal source can also be summed into this path with a gain of 1 V/V to the D2S output pin. [Figure 49](#) shows the midscale buffer to have an extremely flat response through 100 MHz for < 100-mV<sub>PP</sub> swings, while 1 V<sub>PP</sub> can be supported through 80 MHz with a flat response.

From this point on, the diagrams are simplified to not show the power-supply elements. However, the supplies are required by any application, as described in the [Application and Implementation](#) section.

## Device Functional Modes (continued)

### 9.4.1.3 External Connection

In the configuration shown in Figure 92, the bias to PATHSEL (pin 4) is changed in order to select the external input of the OPS. The external D2S output drives a low insertion loss, third-order Bessel filter. The filter in this example is designed with a low frequency insertion loss of 1.2 dB and  $f_{-3dB} = 140$  MHz, and results in an additional insertion loss of 1 dB at 100 MHz. The OPS gain is slightly increased to recover the filter loss, in order to give an input to output gain of 5 V/V. Using an interstage filter between the D2S and the OPS improves the step response by reducing the overshoot.

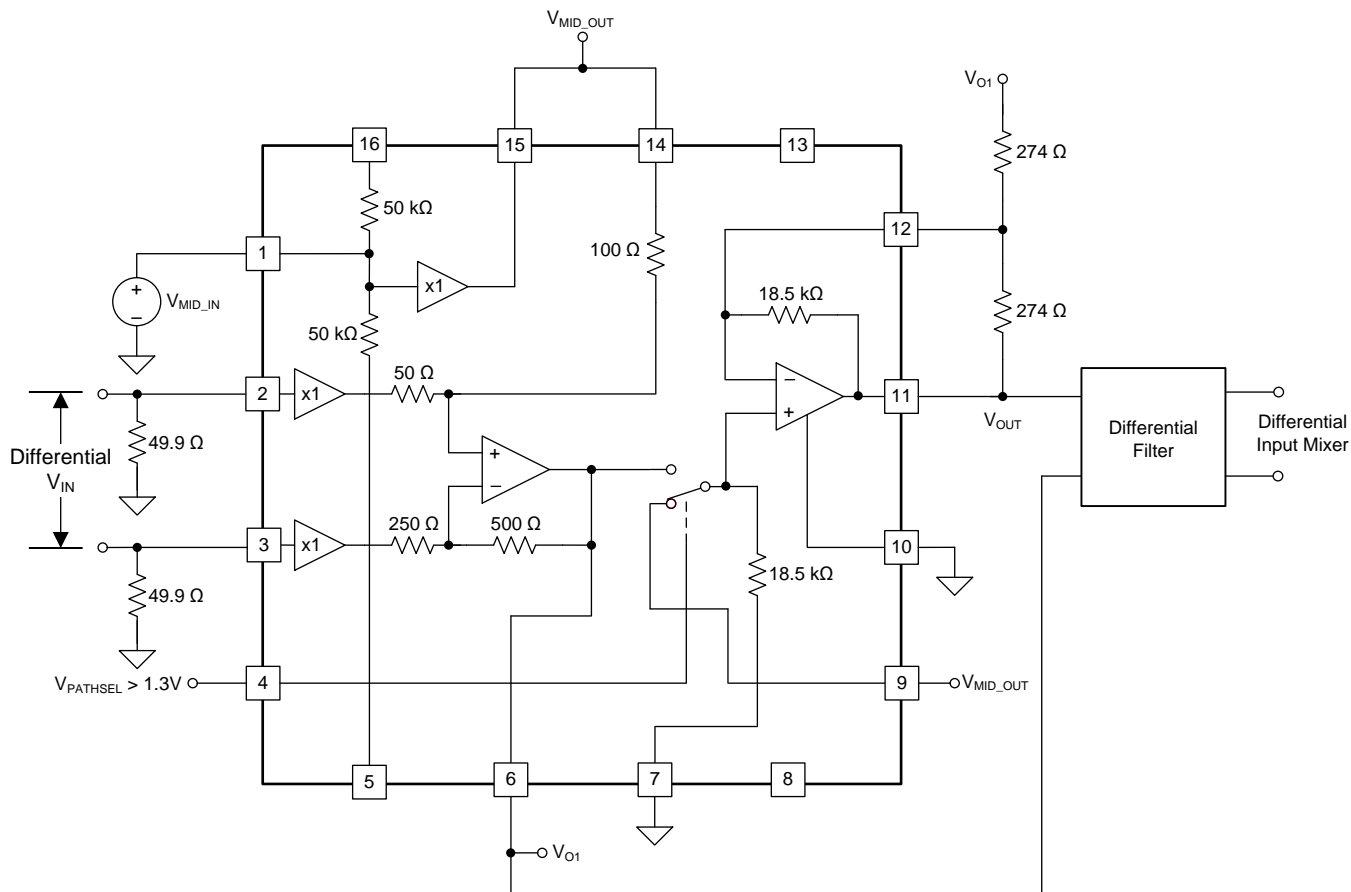

**Figure 92. External Path Configuration With Interstage Low-Pass Filter**

## Device Functional Modes (continued)

### 9.4.3 Differential I/O Voltage Mode

Having two amplifiers available also allows a simple differential I/O implementation with independent output common-mode control, as shown in Figure 94. In this configuration, the D2S provides one side of the differential output, while simultaneously driving the OPS configured in an inverting gain of  $-1$  V/V to provide the differential output on the other side. The output at VMID\_OUT biases the external noninverting input, VIN+ (pin 9). This circuit configuration places the differential input to the output filter at a common-mode voltage, VMID\_OUT.

**Figure 94. Differential I/O Configuration With Independent Output Common-Mode Voltage Control**

## 10 Application and Implementation

### NOTE

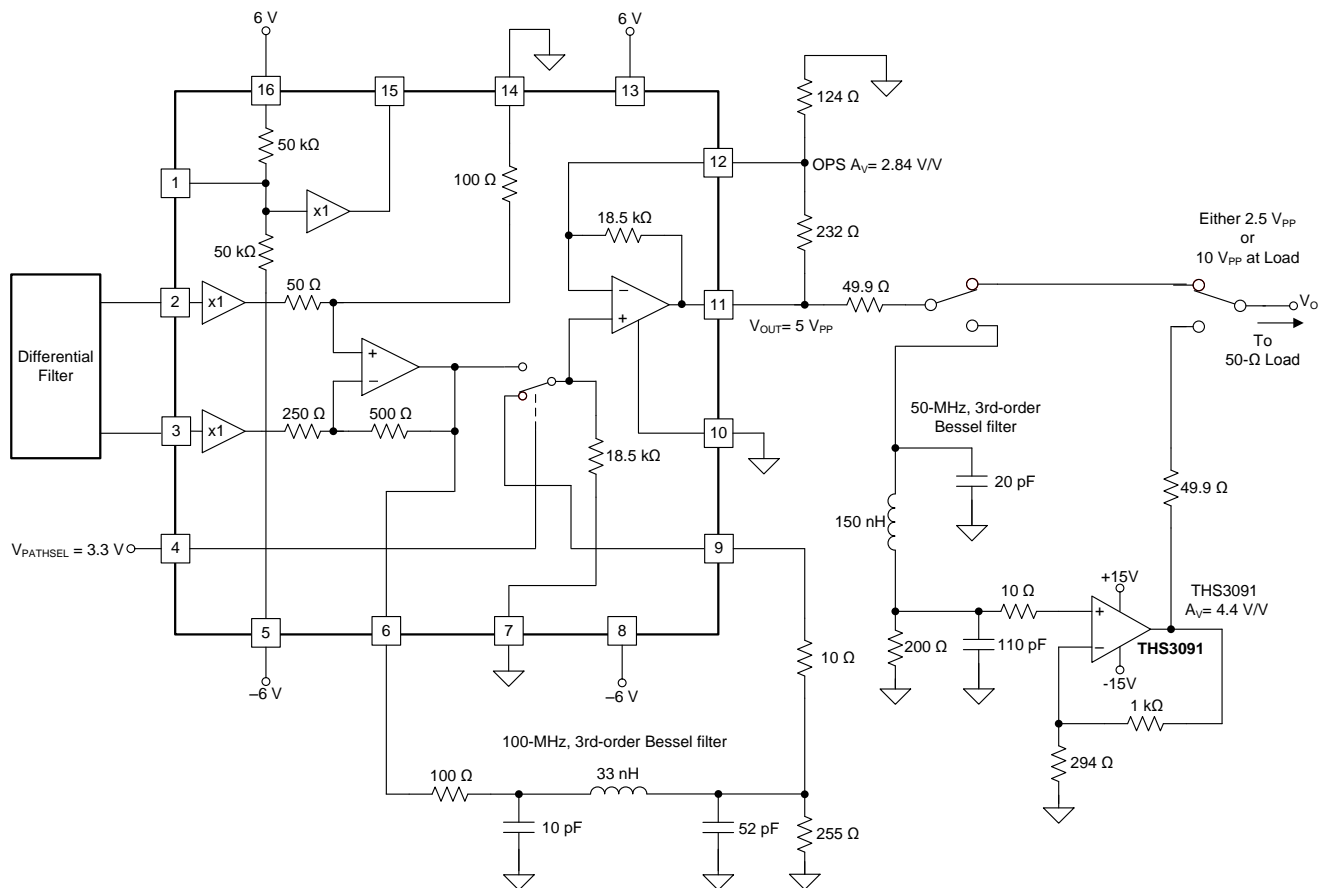

Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI's customers are responsible for determining suitability of components for their purposes. Customers should validate and test their design implementation to confirm system functionality.

### 10.1 Application Information

#### 10.1.1 Typical Applications

The five example designs presented show a good, but not comprehensive, range of the possible solutions that the THS3217 provides. Numerous more configurations are clearly possible to the creative designer.

##### 10.1.1.1 High-Frequency, High-Voltage, Dual-Output Line Driver for AWGs

**Figure 95. Dual-Channel Design: 5 V<sub>PP</sub> at THS3217 Output and 20 V<sub>PP</sub> at THS3091 Output**

##### 10.1.1.1.1 Design Requirements

For this design example, use the parameters listed in [Table 8](#) as the input parameters.

**Table 8. Dual-Output Design Specifications**

DESIGN PARAMETER	EXAMPLE VALUE
High-frequency, THS3217 channel	5-V <sub>PP</sub> , 100-MHz bandwidth
High-voltage, THS3091 channel	20-V <sub>PP</sub> , 40-MHz bandwidth

### 10.1.1.1.2 Detailed Design Procedure

The THS3217 is well suited for high-speed, low-distortion arbitrary waveform generator (AWG) applications commonly used in laboratory equipment. In this typical application, a high-speed, complementary-current-output DAC is used to drive the D2S. The OPS of the THS3217 easily drives a 100-MHz, 2.5-V<sub>PP</sub> signal into a matched 50-Ω load. When a larger output signal is required, consider using the [THS3091](#) as the final driver stage.

A passive RLC filter is commonly used on DAC outputs to reduce the high-frequency content in the DAC steps. The filtering between the DAC output and the input to the D2S reduces higher-order DAC harmonics from feeding into the internal OPS path when the external input path is selected. Feedthrough between the internal and external OPS paths increases with increasing frequency; however, the input filter rolls off the DAC harmonics before the harmonics couple to VOUT (pin 10) through the deselected OPS signal path. [Figure 96](#) shows an example of a doubly-terminated differential filter from the DAC to the THS3217 D2S inputs at pins 2 and 3. The DAC is modeled as two, fixed, 10-mA currents and a differential, ac-current source. The 10-mA dc midscale currents set up the average common-mode voltage at the DAC outputs and D2S inputs at 10 mA × 25 Ω = 0.25 V<sub>CM</sub>. The total voltage swing on the DAC outputs is 0 V to 0.5 V.

**Figure 96. 200-MHz Butterworth Filter Between DAC and D2S Inputs**

Some of the guidelines to consider in this filter design are:

1. The filter cutoff is adjusted to hit a standard value in the standard high-frequency, chip inductors kits.
2. The required filter output capacitance is reduced from the design value of 14.4 pF to 12 pF to account for the D2S input capacitance of 2.4 pF, as reported in the [D2S Electrical Characteristics](#) table.
3. The capacitor at the DAC output pins must also be reduced by the expected DAC output pin capacitance. The DAC output capacitance is often specified as 5 pF, but is usually much lower. Contact the DAC manufacturer for an accurate value.

[Figure 97](#) shows the TINA-simulated filter response for the input-stage filter. The low-frequency 34-dBΩ gain is due to the 50-Ω differential resistance at the DAC output terminals. At 400 MHz, this filter is down 16 dB from the 50-Ω level; it is also very flat through 100 MHz.

**Figure 97. Simulated, Differential-Input Filter Response**

In the example design of [Figure 95](#), a 100-MHz, third-order Bessel filter is placed between the D2S output and the external OPS input. Another 50-MHz, third-order Bessel filter is placed at the input of a very-high, output-swing THS3091 stage. A double-pole, double-throw (DPDT) relay selects the THS3091 path when the internal OPS path is selected in the THS3217. [Figure 95](#) shows this design. The key operational considerations in this design include:

1. When the external OPS path is selected, the  $2\text{-V}_{PP}$  maximum D2S output swing experiences a 1.1-dB insertion loss from the interstage filter between VO1 (pin 6) and VIN+ (pin 9). A standard value inductor is used and the 255- $\Omega$  termination accounts for the internal 18.5-k $\Omega$  element. The 10- $\Omega$  resistor at pin 9 isolates the OPS input from the 52-pF filter capacitor. To recover the insertion loss and produce a maximum  $5\text{-V}_{PP}$  output, the OPS gain is set to 2.84 V/V. When the interstage filter path is selected, the two DPDT relays pass the OPS output on directly from the 49.9- $\Omega$  output matching resistor to  $V_O$ , and the THS3091 can be disabled to conserve power.
2. To deliver  $20\text{ V}_{PP}$  at the  $V_O$  output, select the THS3091 path. Select the internal OPS path to bypass the 100-MHz filter (1.1-dB insertion loss) in order to give a maximum  $5.7\text{-V}_{PP}$  output at VOUT (pin 11). The two DPDT relays switch position, and the 49.9  $\Omega$  at the OPS output becomes part of the 50-MHz, third-order Bessel filter into the THS3091 stage. This filter has a 2-dB insertion loss requiring a gain of 4.4 V/V in the THS3091 to deliver  $20\text{ V}_{PP}$  from the OPS output.
3. [Figure 98](#) and [Figure 99](#) show the frequency response and harmonic distortion performance of the dual output-voltage system. The frequency response is normalized to 0 dB to make bandwidth comparisons easier.

#### 10.1.1.1.3 Application Curves

### 10.1.1.2 High-Voltage Pulse-Generator

Figure 100. Driving a 10- $V_{PP}$  Pulse Output into a 100- $\Omega$  Load With a 55-MHz External Interstage Bessel Filter

#### 10.1.1.2.1 Design Requirements

To design a high-voltage, high-speed pulse generator with minimum overshoot, use the parameters listed in Table 8 as the input parameters.

Table 9. Pulse-Generator Specifications

DESIGN PARAMETER	EXAMPLE VALUE
Power supply	$\pm 7.5$ V
Pulse frequency	10 MHz
Pulse output voltage	10 $V_{PP}$

### 10.1.1.2.2 Detailed Design Procedure

Figure 100 shows an example design using the THS3217 to deliver a 10-V<sub>PP</sub> maximum voltage from a DAC input, and includes an example external, third-order, interstage Bessel filter. Some of the salient considerations for this design include:

1. Reduced DAC output current with increased termination. This example is intended to be used with a current-sourcing DAC with an output compliance voltage of at least 1 V on a 0.5-V common-mode voltage. The 10-mA, single-ended, DAC tail current produces a 0-V to 1-V swing on each 100-Ω termination. The resulting 2-V<sub>PP</sub> differential DAC signal produces a higher SNR signal at the THS3217 inputs.
2. The midscale buffer is not used. The VREF pin is grounded to set the inputs to a 4-V<sub>PP</sub> ground-centered maximum output swing at VO1 (pin 6). The external input to the OPS is selected by setting PATHSEL to 3.3 V (anything over 1.3 V is adequate, or tie this pin to +V<sub>CC</sub> for fixed, external-path operation).
3. The interstage Bessel filter is –0.3-dB flat through 20 MHz, with only 1.6 dB of insertion loss. The filter is designed to be low insertion-loss with relatively high resistor values. The filter uses standard inductor values. The capacitors are also standard-value, and slightly off from the exact filter solution. The final resistor to ground is designed for 500 Ω, but increased here to a standard 511 Ω externally to account for the internal 18.5-kΩ resistor on the external OPS input pin to GND. To isolate the last 47-pF filter capacitor from the OPS input stage, a 10-Ω series resistor is added close to the pin 9 input.
4. The filter adds 1.6 dB of insertion loss that is recovered, to achieve a 10-V<sub>PP</sub> maximum output by designing the OPS for a gain of 3 V/V. Looking at Table 7, this gain setting requires the 232-Ω external R<sub>F</sub> and 113-Ω R<sub>G</sub> to ground for best operation.
5. For 10-V<sub>PP</sub> maximum output, using the ±7.5-V supplies shown here gives adequate headroom in the OPS output stage. The operating maximum supply of 15.8 V requires a 5% tolerance on these ±7.5-V supplies.
6. The Bessel filter gives a very low overshoot full-scale output step-response, as shown in the 10-MHz, ±5-V square wave of Figure 102. The frequency response of the system is shown in Figure 101.

### 10.1.1.2.3 Application Curves

### 10.1.1.3 Single-Supply, AC-Coupled, Piezo Element Driver

Figure 103. Single-Supply, Heavy Capacitive-Load Driving

#### 10.1.1.3.1 Design Requirements

The very-high peak output current and slew rate of the THS3217 OPS make it particularly suitable for driving heavy capacitive loads, such as the piezo elements used in continuous wave (CW) applications that require high-amplitude, sinusoidal-type excitations. The driver is quickly disabled during the receive time when the output TR switch is moved to receive mode. Figure 103 shows an example design using the internal midscale buffer to bias all the stages to midsupply on a single 15-V design. There are many elements to this example that also apply to any single-supply application. The key points here are:

1. The differential DAC input signal is ac-coupled to the D2S input, and the termination resistors are scaled up and biased to midsupply using the output of the midscale buffer,  $V_{MID\_OUT}$  (pin 15). The 10-nF blocking capacitors before the 1.62 kΩ termination resistors set the high-pass pole at 10 kHz.
2. The internal divider resistors of the midscale buffer are decoupled using a 1-μF capacitor on  $VMID\_IN$  (pin 1). Use of the capacitor improves both noise and PSRR through the reference buffer stage. In turn, the noise injected by the bias source is reduced at the various places the buffer output is used.
3.  $V_{MID\_OUT}$  is also applied to the  $VREF$  input (pin 14) to hold the D2S output centered on the single 15-V supply. There is minimal dc current into  $VREF$  (pin 14) because the D2S input buffers operate at the same common-mode voltage,  $V_{MID\_OUT}$ .

4. The D2S output is dc biased at midsupply and delivers two times the differential swing applied at its inputs. Assuming  $2 V_{PP}$  at the D2S inputs implies  $4 V_{PP}$  at the D2S output pins. Lower input swings are supported with the gain in the OPS adjusted to meet the desired output maximum.
5. The filter in [Figure 103](#) is a 0.2-dB ripple, second-order Chebyshev filter at 15 MHz. If the desired maximum frequency is 12 MHz, for instance, this filter is attenuating the HD2 and HD3 out of the D2S by approximately 3 dB and 5 dB, respectively. Increased attenuation can be provided with higher-order filters, but this simple filter does a good job of band-limiting the high-frequency noise from the D2S outputs before the noise gets into the OPS stage.
6. The dc bias voltage at VO1 drives a small dc current into the 18.5-k $\Omega$  resistor to ground at the OPS external input, VIN+ (pin 9). The error voltage due to the bias current will level-shift the dc voltage at the OPS noninverting input through the 105- $\Omega$  filter resistor. This offset will be amplified by the OPS gain since its  $R_G$  element is referenced to the  $V_{MID}$  output with a dc gain of 3.4 V/V.
7. The logic lines are still referenced to ground in this single-supply application. The external path to the OPS is selected by connecting PATHSEL (pin 4) to  $+V_{CC}$ . DISABLE (pin 10) is grounded in this example in order to hold the OPS on. If the disable feature is required by the application, drive the OPS using a standard logic control driver. Note that the midscale buffer output still drives  $R_G$  and  $R_F$  to midsupply in this configuration with the OPS disabled.
8. The  $R_G$  element can be ac coupled to ground through a capacitor to operate at midsupply. [Figure 103](#) shows the midscale buffer driving  $R_G$ , thus eliminating the need for an added capacitor. Using a blocking capacitor moves the dc gain to 1 V/V. The voltage on the external, noninverting input of the OPS sets the dc operating point. Use of a blocking capacitor also lightens the load on the midscale buffer output, and eliminates the bias on  $R_G$  when the OPS is disabled.
9. Piezo element drivers operate in a relatively low-frequency range; therefore, the OPS  $R_F$  is scaled up even further than the values suggested in [Table 7](#). An increased  $R_F$  allows  $R_G$  to also be scaled up, thereby reducing the load on the midscale buffer, and allow a lower series output resistor to be used into the 300-pF capacitive load.
10. The peak charging current into the capacitive load occurs at the peak dV/dT point. Assuming a 12-MHz sinusoid at  $12 V_{PP}$  requires a peak output current from the OPS of  $6 V_{PEAK} \times 2\pi \times 12 \text{ MHz} \times 300 \text{ pF} = 135 \text{ mA}$ . This result matches the rated minimum peak output current of the OPS.

Using a very low series resistor limits the waveform distortion due to the  $I \times R$  drop at the peak charging point around the sinusoidal zero crossing. The 135 mA through 3.3  $\Omega$  causes a 0.45-V peak drop to the load capacitance around zero crossing. The voltage drop across the series output resistor increases the apparent third harmonic distortion at the capacitive load. [Figure 45](#) and [Figure 46](#) show 10- $V_{PP}$  distortion sweeps into various capacitor loads. The results shown in these figures are for the OPS only because the results set the harmonic distortion performance in this example.

#### 10.1.1.4 Output Common-Mode Control Using the Midscale Buffer as a Level Shifter

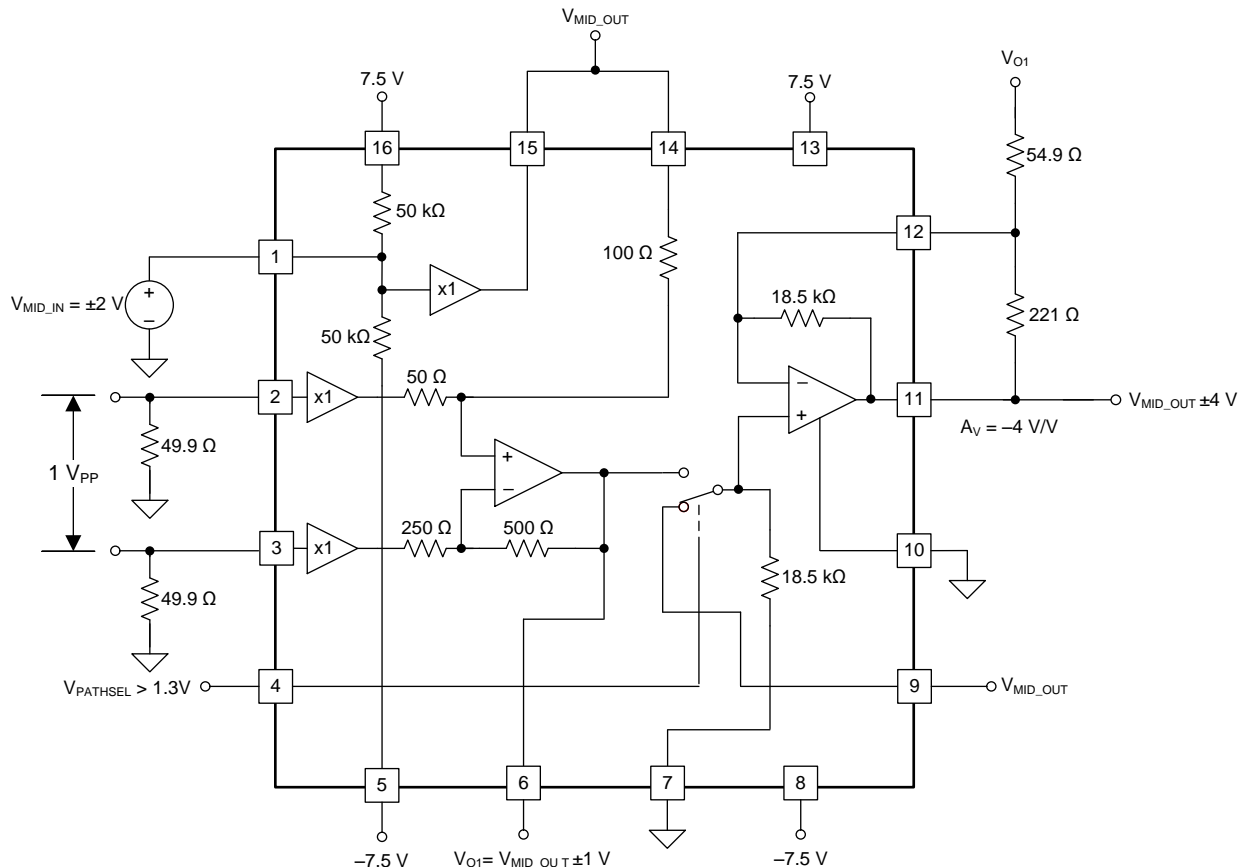

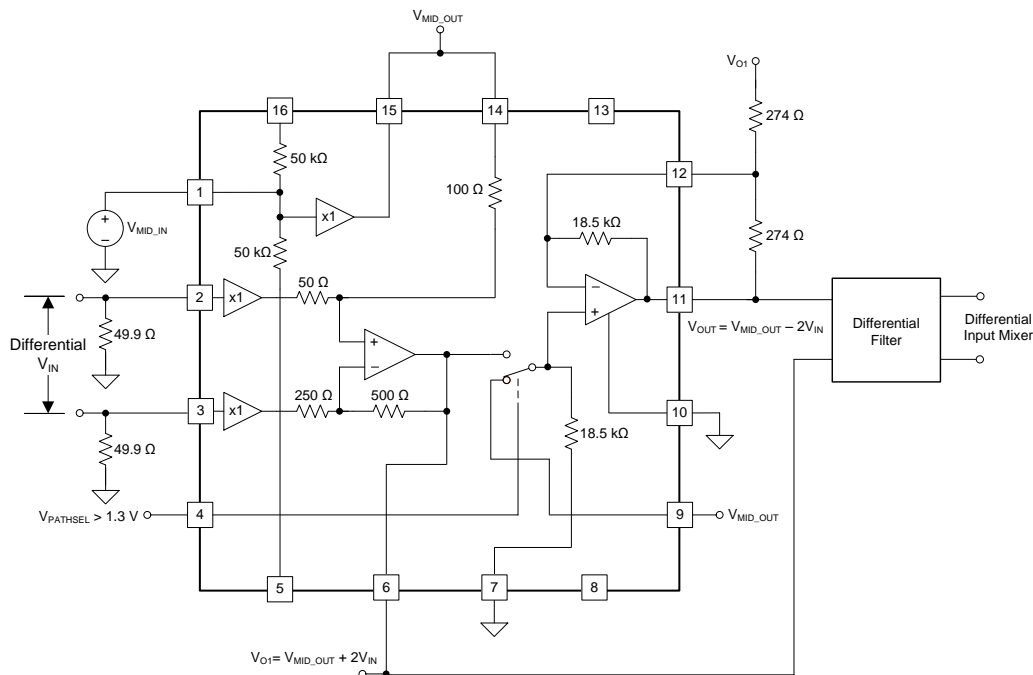

Figure 104. Adding an Output DC Offset Using the Midscale Buffer

##### 10.1.1.4.1 Design Requirements

An easy way to insert a dc offset into the signal channel (without sacrificing any of the DAC dynamic range) is to apply the desired offset at VMID\_IN and use it to bias VREF (pin 14) and VIN+ (pin 9). An example is shown in Figure 104. This example shows a relatively low maximum differential input of 1 V<sub>PP</sub> on any compliance voltage required by the DAC. Other configuration options include:

1. The D2S output is offset using a dc input at VMID\_IN (pin 1). Although shown here as ±2 V, the dc offset expands to ±3.5 V when using ±7.5-V supplies.
2. Connecting VMID\_OUT to the VREF input places the D2S output at the dc offset voltage along with a gain of 2 V/V version of the differential input voltage. The stated range of ±2 V, along with the ±0.5 V out of the upper input buffer, requires a peak output current from VMID\_OUT of 2.5 V / 150 Ω = 16.7 mA. This value is well below the rated minimum linear output current of 40 mA.
3. The dc offset voltage is then applied to the external OPS input. Connecting the circuit in this manner results in no additional dc gain between the D2S and OPS outputs, while it continues to retain the signal gain of the OPS configured as an inverting amplifier. The values of R<sub>F</sub> and R<sub>G</sub> in this application example are derived from Table 4. The OPS is setup for a gain of –4 V/V in this example. Using the resistor values from Table 4 results in the widest bandwidth for the OPS; however, the R<sub>G</sub> = 54.9 Ω resistor presents a heavy load to the D2S output. In such cases, scaling up the resistors in the OPS helps reduce the loading on the D2S output at the expense of reduced OPS bandwidth.
4. No filtering is shown in this example; however, introducing filtering in the OPS R<sub>G</sub> path is certainly possible. In such cases, the R<sub>G</sub> element is also the filter termination resistor. Any filtering adds some insertion loss that can be recovered in the OPS stage.

### 10.1.1.5 Differential I/O Driver With independent Common-Mode Control

**Figure 105. Differential I/O Line Driver**

#### 10.1.1.5.1 Design Requirements

Certain applications require the differential DAC output voltage to be level-translated from one common-mode (compliance) level to a differential output at a different common-mode level. The THS3217 performs this function directly using the very flexible blocks provided internally. Figure 105 shows an example of such an application, where the differential gain is always 4 V/V. The differential gain is fine-tuned down by setting the insertion loss in the differential post-filter. The considerations critical to this application include:

1. The input is dc-coupled with the appropriate termination impedance required by the DAC. Use a high-frequency, antialiasing filter at the input to limit DAC feedthrough in the deselected OPS internal input.
2. The output common-mode control is set with the voltage applied to the VMID buffer input at VMID\_IN (pin 1). The circuit is configured so that the output at VMID\_OUT (pin 15) drives both VREF (pin 14), in order to set the D2S dc output voltage, and VIN+ (pin 9).
3. The D2S output available at VO1 (pin 6) provides one side of the differential-output, and is dc-biased at  $V_{MID\_OUT}$ . This VO1 also drives the  $R_G$  resistor for the OPS in an inverting gain of  $-1$  V/V. The dc bias level at the  $R_G$  input and the V+ input of the OPS are the same voltage; therefore, no level shift through the OPS occurs. The OPS outputs an inverted version of the D2S output signal at the same common-mode voltage ( $V_{MID\_OUT}$ ). The wideband, differential signal with independent output common-mode voltage control can now be applied to a differential filter and on to the next stage.
4. Make sure that the differential filter only has differential resistors and capacitors. Termination resistors to ground level shift the input common-mode voltage, while differential resistors transfers the desired  $V_{MID\_OUT}$  directly through the filter.
5. If the desired  $V_{MID\_OUT} +$  differential signal combined clips in the OPS or D2S stages, offset the supplies to gain headroom. For instance, if a 5-V output common-mode voltage is required with a 10-V<sub>PP</sub> differential signal, the OPS and D2S must deliver 2.5-V to 7.5-V output swings. The D2S has the higher headroom requirement at 1.55 V (max). Operating the THS3217 with  $-5$  V and  $+10$  V supplies stays within the rated maximum of 15.8 V total supply range, and provide adequate headroom for the positive offset swing requirement. Note that the logic lines are still referenced to GND by pin 7. Tying PATHSEL (pin 4) to  $+V_{CC}$  holds this design in the external path mode required.

## 11 Power Supply Recommendations

The THS3217 typically operates on balanced, split supplies. The specifications and characterization plots use  $\pm 6$  V in most cases. The full operating range for the THS3217 spans  $\pm 4$  V to  $\pm 7.9$  V. The input and output stages have separate supply pins that are isolated internally.

The recommended external supply configuration brings  $\pm V_{CC}$  into the output stage first, then back to the input stage connections through a  $\pi$ -filter comprised of ferrite beads and added decoupling capacitors at +VCC2 (pin 16) and -VCC2 (pin 5). Figure 106 shows an example decoupling configuration.

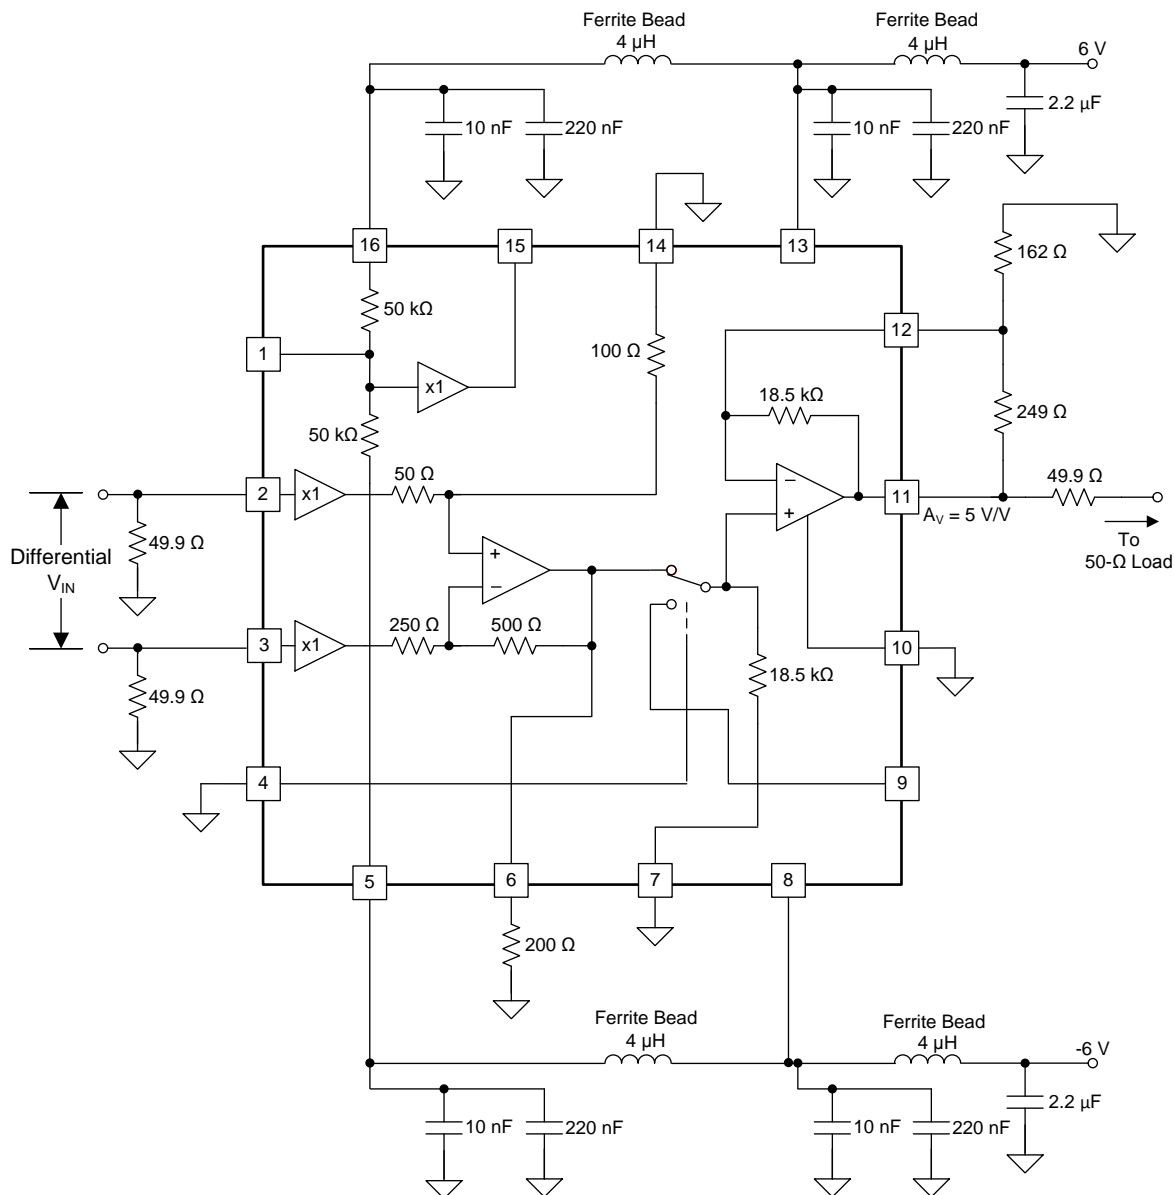

Figure 106. Recommended Power-Supply Configuration

The ferrite bead acts to break the feedback loop from the output stage load currents back into the D2S and midscale buffer stages. Operate the two positive supply pins and the two negative supply pins at the same voltage. Using separate sources on the two pins risks forward-biasing the on-chip parallel diodes connecting the two supply inputs together. +VCC1 (pin 13) and +VCC2 (pin 16) have two parallel diodes that are normally off if the voltage at the two pins are equal. The same is true for –VCC1 (pin 8) and –VCC2 (pin 5).

The THS3217 provides considerable flexibility in the supply voltage settings. The overriding consideration is always satisfying the required headroom to the supplies on all the I/O paths. The logic controls on PATHSEL (pin 4) and DISABLE (pin 10) are intended to operate ground referenced regardless of supplies used. The ground connection on pin 7 is used to set the reference.

Power savings are certainly possible by operating with only the minimum required supplies for the intended swings at each of the pins. For instance, consider an example design operating with a current-sinking DAC with the input common-mode voltage at 3 V, with an output swing at the D2S output of  $\pm 1$  V. Looking at just the D2S stage under these conditions, the minimum positive supply is  $3 V_{CM}$  + the maximum input headroom of 1.5 V to the positive supply, resulting in a minimum 4.5-V supply for this operation. The  $\pm 1$ -V output at VO1 (pin 6) along with the D2S output headroom sets the minimum negative supply voltage. The maximum 1.65-V headroom gives a possible minimum negative supply of –2.65 V. However, the minimum operating total of 8 V increases the negative supply to –3.5 V.

If the  $\pm 1$ -V swing is then amplified by the OPS, the output swing and headroom requirements set the minimum operating supply. For instance, if the OPS is operating at a gain of 2.5 V/V, the  $\pm 2.5$ -V output requires a maximum headroom of 1.4 V to either supply. Achieving a 1.4-V headroom requires a minimum balanced supply of  $\pm 3.9$  V. However, the input stage overrides the positive side because the required minimum is 4.5 V, while the negative increases to –3.9 V. This example of absolute minimum supplies saves power. Using a typical 56-mA quiescent current for all stages, going to the minimum 8.4 V total across the device, uses 470 mW of quiescent power versus the 672 mW if a simple  $\pm 6$ -V supply is applied. However, ac performance degrades with the lower headroom. For more power-sensitive applications, consider adjusting the supplies to the minimum required on each side.

## 11.1 Thermal Considerations

The internal power for the THS3217 is a combination of its quiescent power and load power. The quiescent power is simply the total supply voltage times the supply current. This current is trimmed to reduce power dissipation variation and minimize variations in the ac performance. At a  $\pm 7.5$ -V supply, the maximum supply current of 57 mA dissipates 855 mW of quiescent power. The worst-case load power occurs if the output is at  $\frac{1}{2}$  the single-sided supply voltage driving a dc load. Placing a  $\pm 3.75$ -V dc output into 100  $\Omega$  adds another  $37.5 \text{ mA} \times 3.75 \text{ V} = 140 \text{ mW}$  of internal power. This total of approximately 1 W of internal dissipation requires the thermal pad be connected to a good heat-spreading ground plane to hold the internal junction temperatures below the rated maximum of 150°C.

The thermal impedance is approximately 45 °C/W with the thermal pad connected. For 1 W of internal power dissipation there is a 45°C (approximate) rise in the junction temperature from ambient. Designing for the intended 85°C maximum ambient temperature results in a maximum junction temperature of 130°C.

## 12 Layout

### 12.1 Layout Guidelines

High-speed amplifier designs require careful attention to board layout in order to achieve the performance specified in the data sheets. Poor layout techniques can lead to increased parasitics from the board and external components resulting in suboptimal performance, and also instability in the form of oscillations. The THS3217 evaluation module (EVM) serves as a good reference for proper, high-speed layout methodology. The EVM includes numerous extra elements needed for lab characterization, and also additional features that are useful in certain applications. These additional components can be eliminated on the end system if not required by the application. General suggestions for the design and layout of high-speed, signal-path solutions include:

1. Minimize parasitic capacitance to any ac ground for all of the signal I/O pins. Parasitic capacitance on the output and input pins can cause instability. To reduce unwanted capacitance, a window around the signal I/O pins should be opened on all of the ground and power planes around those pins. On other areas of the board continuous ground and power planes are preferred for signal routing with matched impedance traces for longer runs.
2. Use good, high-frequency decoupling capacitors (0.1  $\mu\text{F}$ ) on the ground plane at the device power pins. Higher value capacitors (2.2  $\mu\text{F}$ ) are required, but may be placed further from the device power pins and shared among devices. For best high-frequency decoupling, consider X2Y supply-decoupling capacitors that offer a much higher self-resonance frequency over standard capacitors. Avoid narrow power and ground traces to minimize inductance between the pins and the decoupling capacitors. Follow the power-supply guidelines recommended in the [Power Supply Recommendations](#) section.
3. Careful selection and placement of external components preserve the high-frequency performance of the THS3217. Use low-reactance type resistors. Surface-mount resistors work best, and allow a tighter overall layout. Keep the printed circuit board (PCB) trace length as short as possible. Never use wire-bound type resistors in a high-frequency application. The output pin and inverting input pins are the most sensitive to parasitic capacitance; therefore, always position the feedback and series output resistors, if any, as close as possible to the inverting input pins and output pins. Place other network components, such as input termination resistors, close to the gain-setting resistors.
4. When using differential signal routing over any appreciable distance, use microstrip layout techniques with matched impedance traces. On differential lines, like those on the D2S inputs, match the routing in order to minimize common-mode noise effects and improve HD2 performance.
5. The input summing junction of the OPS is very sensitive to parasitic capacitance. Connect the  $R_G$  element into the summing junction with minimal trace length to the device pin side of the resistor. The other side of  $R_G$  can have more trace length if needed to the source or to ground. For best results, do not socket a high-speed part like the THS3217. The additional lead length and pin-to-pin capacitance introduced by the socket can create an extremely troublesome parasitic network that can make it almost impossible to achieve a smooth, stable frequency response. Best results are obtained by soldering the THS3217 directly onto the board.

## 13 器件和文档支持

### 13.1 器件支持

#### 13.1.1 开发支持

##### 13.1.1.1 TINA-TI™ (免费软件下载)

TINA™是一款简单、功能强大且易于使用的电路仿真程序，此程序基于 SPICE 引擎。TINA-TI 是 TINA 软件的一款免费全功能版本，除了一系列无源和有源模型外，此版本软件还预先载入了一个宏模型库。TINA-TI 提供所有传统的 SPICE 直流、瞬态和频域分析，以及其他设计功能。

TINA-TI 可从 Analog eLab Design Center (模拟电子实验室设计中心) [免费下载](#)，它提供全面的后续处理能力，使得用户能够以多种方式形成结果。虚拟仪器提供选择输入波形和探测电路节点、电压和波形的功能，从而创建一个动态的快速入门工具。

#### 注

这些文件需要安装 TINA 软件 (由 DesignSoft™提供) 或者 TINA-TI 软件。请从 [TINA-TI 文件夹](#) 中下载免费的 TINA-TI 软件。

## PACKAGING INFORMATION

Orderable Device	Status (1)	Package Type	Package Drawing	Pins	Package Qty	Eco Plan (2)	Lead finish/ Ball material (6)	MSL Peak Temp (3)	Op Temp (°C)	Device Marking (4/5)	Samples
THS3217IRGVR	ACTIVE	VQFN	RGV	16	2500	RoHS & Green	NIPDAU	Level-2-260C-1 YEAR	-40 to 85	THS3217 IRGV	<a href="#">Samples</a>
THS3217IRGVT	ACTIVE	VQFN	RGV	16	250	RoHS & Green	NIPDAU	Level-2-260C-1 YEAR	-40 to 85	THS3217 IRGV	<a href="#">Samples</a>

(1) The marketing status values are defined as follows:

**ACTIVE:** Product device recommended for new designs.

**LIFEBUY:** TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.

**NRND:** Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.

**PREVIEW:** Device has been announced but is not in production. Samples may or may not be available.

**OBsolete:** TI has discontinued the production of the device.

(2) **RoHS:** TI defines "RoHS" to mean semiconductor products that are compliant with the current EU RoHS requirements for all 10 RoHS substances, including the requirement that RoHS substance do not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, "RoHS" products are suitable for use in specified lead-free processes. TI may reference these types of products as "Pb-Free".

**RoHS Exempt:** TI defines "RoHS Exempt" to mean products that contain lead but are compliant with EU RoHS pursuant to a specific EU RoHS exemption.

**Green:** TI defines "Green" to mean the content of Chlorine (Cl) and Bromine (Br) based flame retardants meet JS709B low halogen requirements of <=1000ppm threshold. Antimony trioxide based flame retardants must also meet the <=1000ppm threshold requirement.

(3) MSL, Peak Temp. - The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

(4) There may be additional marking, which relates to the logo, the lot trace code information, or the environmental category on the device.

(5) Multiple Device Markings will be inside parentheses. Only one Device Marking contained in parentheses and separated by a "~" will appear on a device. If a line is indented then it is a continuation of the previous line and the two combined represent the entire Device Marking for that device.

(6) Lead finish/Ball material - Orderable Devices may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead finish/Ball material values may wrap to two lines if the finish value exceeds the maximum column width.

**Important Information and Disclaimer:** The information provided on this page represents TI's knowledge and belief as of the date that it is provided. TI bases its knowledge and belief on information provided by third parties, and makes no representation or warranty as to the accuracy of such information. Efforts are underway to better integrate information from third parties. TI has taken and continues to take reasonable steps to provide representative and accurate information but may not have conducted destructive testing or chemical analysis on incoming materials and chemicals. TI and TI suppliers consider certain information to be proprietary, and thus CAS numbers and other limited information may not be available for release.

In no event shall TI's liability arising out of such information exceed the total purchase price of the TI part(s) at issue in this document sold by TI to Customer on an annual basis.

PLASTIC QUAD FLATPACK NO-LEAD

4203497/F 06/11

- NOTES:
- All linear dimensions are in millimeters. Dimensioning and tolerancing per ASME Y14.5M-1994.
  - This drawing is subject to change without notice.
  - Quad Flatpack, No-leads (QFN) package configuration.
  - The package thermal pad must be soldered to the board for thermal and mechanical performance.
  - See the additional figure in the Product Data Sheet for details regarding the exposed thermal pad features and dimensions.
  - Falls within JEDEC MO-220.

RGV (S-PVQFN-N16)

PLASTIC QUAD FLATPACK NO-LEAD

## THERMAL INFORMATION

This package incorporates an exposed thermal pad that is designed to be attached directly to an external heatsink. The thermal pad must be soldered directly to the printed circuit board (PCB). After soldering, the PCB can be used as a heatsink. In addition, through the use of thermal vias, the thermal pad can be attached directly to the appropriate copper plane shown in the electrical schematic for the device, or alternatively, can be attached to a special heatsink structure designed into the PCB. This design optimizes the heat transfer from the integrated circuit (IC).

For information on the Quad Flatpack No-Lead (QFN) package and its advantages, refer to Application Report, QFN/SON PCB Attachment, Texas Instruments Literature No. SLUA271. This document is available at [www.ti.com](http://www.ti.com).

The exposed thermal pad dimensions for this package are shown in the following illustration.

Bottom View

Exposed Thermal Pad Dimensions
