# TAS5414C 四通道汽车售后加装 D 类放大器

#### 特性 1

Texas

INSTRUMENTS

- 四通道单端模拟输入 D 类音频放大器
- 在 10% 总谐波失真 (THD) + N 上典型输出功率
  - 14.4V时,为4Ω负载每通道输出功率为28W
  - 14.4V时,为 2Ω 负载每通道输出功率为 50W
  - 24V时,为4Ω负载每通道输出功率为79W
  - 24V时,为 2Ω 负载每通道输出功率为 150W (PBTL)
- 通道可被并联 (PBTL),适用于高电流 应用
- THD + N < 0.02%, 1kHz, 为 4Ω 负载提供 1W
- 已获专利的杂音抑制技术
  - 具有增益斜波控制的软静音
  - 共模斜波修整
- 已获专利的 AM 干扰避免
- 已获专利的逐周期电流限制
- 75dB 电源抑制比 (PSRR)
- 针对器件配置和控制的 4 地址 I<sup>2</sup>C 串行接口
- 通道增益: 12dB, 20dB, 26dB, 32dB
- 负载诊断功能:
  - 输出打开和短接负载
  - 输出到电源和输出到接地短接
  - 已获专利的高频扬声器侦测
- 保护和监控功能:
  - 短路保护
  - 负载突降保护达 50V
  - 偶然开放式接地和电源容错
  - 已获专利的在音乐播放的同时进行输出直流电平 侦测
  - 过热保护
  - 过压和欠压条件
  - 片段侦测器
- 64 引脚四方扁平无引线 (QFP) (PHD) 功率封装 (散热片朝上)
- -20°C 至 105°C 环境温度范围
- 2 应用
- 售后加装音响主机
- 售后加装外部音频放大器

# 3 说明

TAS5414C器件是一款四通道 D 类音频放大器,专为 汽车类音响主机和外部放大器模块而设计。在 14.4V 电源供电下,能够以低于 1% 的 THD+N 持续为 4 $\Omega$  负 载提供四通道 23W 功率。每个通道还能够以 1% 的 THD+N 为 2Ω 负载提供 38W 的功率。TAS5414C 采 用单端模拟量输入。此器件的 D 类数字脉宽调制 (PWM) 拓扑可大大提升传统线性放大器解决方案的效 率。在正常音乐播放条件下,这有助于将放大器功耗减 降低 10%。该器件具有内置负载诊断功能,用于检测 和诊断误接的输出,从而帮助缩短制造过程中的测试时 间。

#### 器件信息(1)

| 器件型号     | 封装         | 封装尺寸(标称值)         |
|----------|------------|-------------------|
| TAS5414C | HTQFP (64) | 14.00mm x 14.00mm |

(1) 如需了解所有可用封装,请参见数据表末尾的可订购产品附 录。

#### 每通道效率与功耗对比

| OUT3_P   | 36   | PO                  | + polarity output for bridge 3  |
| OUT4_M   | 34   | PO                  | - polarity output for bridge 4  |
| OUT4_P   | 33   | PO                  | + polarity output for bridge 4  |
| PVDD     | 27, 28, 29, 52, 53, 54   | PWR                 | PVDD supply   |
| REXT     | 10   | AI                  | Precision resistor pin to set analog reference  |
| SCL      | 64   | DI                  | I <sup>2</sup> C clock input from system I <sup>2</sup> C master                              |
| SDA      | 63   | DI/DO               | I <sup>2</sup> C data I/O for communication with system I <sup>2</sup> C master               |
| STANDBY  | 4  | DI                  | Active-low STANDBY pin. Standby (low), power up (high)  |
|          |  |                     |   |

(1) DI = digital input, DO = digital output, AI = analog input, ARTN = analog signal return, PWR = power supply, PBY = power bypass, PO = power output, GND = ground, CP = charge pump.

## 6 Specifications

## 6.1 Absolute Maximum Ratings

over operating free-air temperature range (unless otherwise noted)

|                                   |  |  | MIN  | MAX   | UNIT |
|-----------------------------------|--|--|------|-------|------|
| PVDD                              | DC supply voltage range  | Relative to GND                            | -0.3 | 30    | V    |
| PVDD <sub>MAX</sub>               | Pulsed supply voltage range  | t ≤ 100 ms exposure                        | -1   | 50    | V    |
| PVDD <sub>RAMP</sub>              | Supply voltage ramp rate   |  |      | 15    | V/ms |
| I <sub>PVDD</sub>                 | Externally imposed dc supply current per PVDD or GND pin                         |  |      | ±12   | А    |
| I <sub>PVDD_MAX</sub>             | Pulsed supply current per PVDD pin (one shot)                                    | t < 100 ms                                 |      | 17    | А    |
| I <sub>O</sub>                    | Maximum allowed dc current per output pin  |  |      | ±13.5 | А    |
| I <sub>O_MAX</sub> <sup>(1)</sup> | Pulsed output current per output pin (single pulse)                              | t < 100 ms                                 |      | ±17   | А    |
| I <sub>IN_MAX</sub>               | Maximum current, all digital and analog input pins <sup>(2)</sup>                | DC or pulsed                               |      | ±1    | mA   |
| I <sub>MUTE_MAX</sub>             | Maximum current on MUTE pin  | DC or pulsed                               |      | ±20   | mA   |
| I <sub>IN_ODMAX</sub>             | Maximum sink current for open-drain pins   |  |      | 7     | mA   |
| V <sub>LOGIC</sub>                | Input voltage range for pin relative to GND (SCL, SDA, I2C_ADDR pins)            | Supply voltage range:<br>6V < PVDD < 24 V  | -0.3 | 6     | V    |
| V <sub>MUTE</sub>                 | Voltage range for MUTE pin relative to GND                                       | Supply voltage range:<br>6 V < PVDD < 24 V | -0.3 | 7.5   | V    |
| V <sub>STANDBY</sub>              | Input voltage range for STANDBY pin  | Supply voltage range:<br>6 V < PVDD < 24 V | -0.3 | 5.5   | V    |
| V <sub>OSC_SYNC</sub>             | Input voltage range for OSC_SYNC pin relative to GND                             | Supply voltage range:<br>6 V < PVDD < 24 V | -0.3 | 3.6   | V    |
| V <sub>GND</sub>                  | Maximum voltage between GND pins   |  |      | ±0.3  | V    |
| V <sub>AIN_AC_MAX</sub>           | Maximum ac-coupled input voltage for TAS5414C <sup>(2)</sup> , analog input pins | Supply voltage range:<br>6 V < PVDD < 24 V |      | 1.9   | Vrms |
| TJ                                | Maximum operating junction temperature range                                     |  | -55  | 150   | °C   |
| T <sub>stg</sub>                  | Storage temperature  |  | -55  | 150   | °C   |

(1) Pulsed current ratings are maximum survivable currents externally applied to the device. The device may encounter high currents during reverse-battery, fortuitous open-ground, and fortuitous open-supply fault conditions.

(2) See the Application Information section for information on analog input voltage and ac coupling.

### 6.2 ESD Ratings

|                    |   |  |  | VALUE         | UNIT |
|--------------------|---|--|--|---------------|------|
|                    | Human body model (HBM), per AEC Q100-002 <sup>(1)</sup> |  | ±2500  | V             |      |
|                    |   |  | Corner pins excluding SCL                        | ±750          |      |
| V <sub>(ESD)</sub> | Electrostatic discharge                                 | Charged device model (CDM),<br>per AEC Q100-011<br>PHD Package | All pins (including SCL) except<br>CP and CP_Top | ±600          | V    |
|                    |   |  | CP and CP_Top pins                               | ±2500<br>±750 |      |

(1) AEC Q100-002 indicates HBM stressing is done in accordance with the ANSI/ESDA/JEDEC JS-001 specification.

## 6.3 Recommended Operating Conditions<sup>(1)</sup>

|                                 |   |   | MIN | TYP  | MAX                   | UNIT |
|---------------------------------|---|---|-----|------|-----------------------|------|
| PVDD <sub>OP</sub>              | DC supply voltage range relative to GND |   | 6   | 14.4 | 24                    | V    |
| V <sub>AIN</sub> <sup>(2)</sup> | Analog audio input signal level         | AC-coupled input voltage  | 0   |      | 0.25–1 <sup>(3)</sup> | Vrms |
| T <sub>A</sub>                  | Ambient temperature                     |   | -20 |      | 105                   | °C   |
| TJ                              | Junction temperature                    | An adequate heat sink is required to keep $T_{\rm J}$ within specified range. | -40 |      | 115                   | °C   |
| RL                              | Nominal speaker load impedance          |   | 2   | 4    |                       | Ω    |

(1) The *Recommended Operating Conditions* table specifies only that the device is functional in the given range. See the *Electrical Characteristics* table for specified performance limits.

(2) Signal input for full unclipped output with gains of 32 dB, 26 dB, 20 dB, and 12 dB

(3) Maximum recommended input voltage is determined by the gain setting.

# **Typical Characteristics (continued)**

## 7 Detailed Description

#### 7.1 Overview

The TAS5414C is a single-chip, four-channel, analog-input audio amplifier. The design uses an ultra-efficient class-D technology developed by Texas Instruments. This technology allows for reduced power consumption, reduced heat, and reduced peak currents in the electrical system. The device realizes an audio sound system design with smaller size and lower weight than traditional class-AB solutions.

There are eight core design blocks:

- Preamplifier
- PWM
- Gate drive
- Power FETs
- Diagnostics
- Protection
- Power supply
- I<sup>2</sup>C serial communication bus

### 7.2 Functional Block Diagram

## 7.3 Feature Descption

#### 7.3.1 Preamplifier

www.ti.com.cn

The preamplifier is a high-input-impedance, low-noise, low-offset-voltage input stage with adjustable gain. The high input impedance allows the use of low-cost input capacitors while still achieving extended low-frequency response. A dedicated, internally regulated supply pwoers the preamplifier, giving it excellent noise immunity and channel separation. The preamplifier also includes:

- 1. **Mute Pop-and-Click Control** The device ramps the gain gradually when receiving a mute or play command. The start or stopping of switching in a class-D amplifier can cause another form of click and pop. The TAS5414C incorporates a patented method to reduce the pop energy during the switching startup and shutdown sequence. Fault conditions require rapid protection response by the TAS5414C, which does not have time to ramp the gain down in a pop-free manner. The device transitions into Hi-Z mode when encountering an OV, UV, OC, OT, or dc fault. Also, activation of the STANDBY pin may not be pop-free.
- Gain Control Setting of gains for the four channels occurs in the preamplifier via I<sup>2</sup>C control registers, outside of the global feedback resistors of the device, thus allowing for stability of the system at all gain settings with properly loaded conditions.

#### 7.3.2 Pulse-Width Modulator (PWM)

The PWM converts the analog signal from the preamplifier into a switched signal of varying duty cycle. This is the critical stage that defines the class-D architecture. In the TAS5414C, the modulator is an advanced design with high bandwidth, low noise, low distortion, excellent stability, and full 0–100% modulation capability. The patented PWM uses clipping recovery circuitry to eliminate the deep saturation characteristic of PWMs when the input signal exceeds the modulator waveform.

#### 7.3.3 Gate Drive

The gate driver accepts the low-voltage PWM signal and level-shifts it to drive a high-current, full-bridge, power FET stage. The device uses proprietary techniques to optimize EMI and audio performance.

#### 7.3.4 Power FETs

The BTL output for each channel comprises four rugged N-channel 30-V 65-m $\Omega$  FETs for high efficiency and maximum power transfer to the load. These FETs can handle large voltage transients during load dump.

#### 7.3.5 Load Diagnostics

The device incorporates load diagnostic circuitry designed to help pinpoint the nature of output misconnections during installation. The TAS5414C includes functions for detecting and determining the status of output connections. The device supports the following diagnostics:

- Short to GND
- Short to PVDD
- Short across load
- Open load
- Tweeter detection

Reporting to the system of the presence of <u>any of the short</u> or open conditions occurs via I<sup>2</sup>C register read. One can read the tweeter-detect status from the CLIP\_OTW pin when properly configured.

1. **Output Short and Open Diagnostics** — The device contains circuitry designed to detect shorts and open conditions on the outputs. Invocation of the load diagnostic function can only occur when the output is in the Hi-Z mode. There are four phases of test during load diagnostics and two levels of test. In the full level, all channels must be in the Hi-Z state. Testing covers all four phases on each channel, all four channels at the same time. When fewer than four channels are in Hi-Z, the reduced level of test is the only available option. In the reduced level, the only tests available are short to PVDD and short to GND. Load diagnostics can occur at power up before moving the amplifier out of Hi-Z mode. If the amplifier is already in play mode, it must *Mute* and then *Hi-Z* before performing the load diagnostics. By performing the mute function, the normal pop- and click-free transitions occur before the diagnostics begin. Performance of the diagnostics is as shown in Figure 10. Figure 11 shows the impedance ranges for the open-load and shorted-load diagnostics. Reading the results of the diagnostics is from the diagnostic register via I<sup>2</sup>C for each channel. With the default settings and MUTE capacitor, the S2G and S2P phase take approximately 20 ms each, the OL phase

#### Feature Descption (continued)

takes approximately 100 ms, and the SL takes approximately 230 ms. In I<sup>2</sup>C register 0x10, bit D4 can extend the test time for S2P and S2G to 80 ms each. To prevent false S2G and S2P faults, this time extension is necessary if the output pins have a capacitance higher than 680 nF to ground .

Figure 10. Load Diagnostics Sequence of Events

Figure 11. Open- and Shorted-Load Detection

2. Tweeter Detection — Tweeter detection is an alternate operating mode used to determine the proper connection of a frequency-dependent load (such as a speaker with a crossover). Invoking of weeter detection is via I<sup>2</sup>C, with individual testing of all four channels recommended. Tweeter detection uses the average cycle-by-cycle current limit circuit (see CBC section) to measure the current delivered to the load. The proper implementation of this diagnostic function depends on the amplitude of a user-supplied test signal and on the impedance-versus-frequency curve of the acoustic load. The system (external to the TAS5414C) must generate a signal to which the load responds. The frequency and amplitude of this signal must be calibrated by the user to result in a current draw that is greater than the tweeter detection threshold when the load

T0188-01

## Feature Descption (continued)

under test is present, and less than the detection threshold if the load is unconnected. The current level for the tweeter detection threshold, as well as the maximum current that can safely be delivered to a load when in tweeter-detection mode, is in the Electrical Characteristics section of the data sheet. Reporting of the tweeter-detection results is on the CLIP\_OTW pin during the application of the test signal. With tweeter detection activated (indicating that the tested load is present), pulses on the CLIP\_OTW pin begin to toggle. The pulses on the CLIP\_OTW pins report low whenever the current exceeds the detection threshold, and the pin remains low until the current no longer exceeds the threshold. The minimum low-pulse period that one can expect is equal to one period of the switching frequency. Having an input signal that increases the duration of detector activation (for example, increasing the amplitude of the input signal) increases the for reports amount of time which the pin low. NOTE: Because tweeter detection is an alternate operating mode, place the channels to be tested in Play mode (via register 0x0C) after tweeter detection has been activated in order to commence the detection process. Additionally, set up the CLIP\_OTW pin via register 0x0A to report the results of tweeter detection.

### 7.3.6 Protection and Monitoring

- Cycle-By-Cycle Current Limit (CBC) The CBC current-limiting circuit terminates each PWM pulse to limit the output current flow to the average current limit (I<sub>LIM</sub>) threshold. The overall effect on the audio in the case of a current overload is quite similar to a voltage-clipping event, temporarily limiting power at the peaks of the musical signal and normal operation continues without disruption on removal of the overload. The TAS5414C does not prematurely shut down in this condition. All four channels continue in play mode and pass signal.
- 2. Overcurrent Shutdown (OCSD) Under severe short-circuit events, such as a short to PVDD or ground, the device uses a peak-current detector, and the affected channel shuts down in 200 µs to 390 µs if the conditions are severe enough. The shutdown speed depends on a number of factors, such as the impedance of the short circuit, supply voltage, and switching frequency. Only the shorted channels shut down in such a scenario. The user may restart the affected channel via I<sup>2</sup>C. An OCSD event activates the fault pin, and the I<sup>2</sup>C fault register saves a record of the affected channels. If the supply or ground short is strong enough to exceed the peak current threshold but not severe enough to trigger the OCSD, the peak current limiter prevents excess current from damaging the output FETs, and operation returns to normal after the short is removed.
- 3. DC Detect—This circuit detects a dc offset at the output of the amplifier continuously during normal operation. If the dc offset reaches the level defined in the l<sup>2</sup>C registers for the specified time period, the circuit triggers. By default, a dc detection event does not shut the output down. Disabling and enabling the shutdown function is via l<sup>2</sup>C. If enabled, the triggered channel shuts down, but the others remain playing, but with the FAULT pin asserted. The l<sup>2</sup>C registers define the dc level.
- 4. Clip Detect—The clip detect circuit alerts the user to the presence of a 100% duty-cycle PWM due to a clipped waveform. When this occurs, a signal passed to the CLIP\_OTW pin asserts it until the 100% duty-cycle PWM signal is no longer present. All four channels connect to the same CLIP\_OTW pin. Through I<sup>2</sup>C, one can change the CLIP\_OTW signal clip-only, OTW-only, or both. A fourth mode, used only during diagnostics, is the option to report tweeter detection events on this pin (see the *Tweeter Detection* section). The microcontroller in the system can monitor the signal at the CLIP\_OTW pin, and may have a configuration that reduces the volume to all four channels in an active clipping-prevention circuit.
- 5. Overtemperature Warning (OTW), Overtemperature Shutdown (OTSD) and Thermal Foldback By default, the CLIP\_OTW pin setting indicates an OTW. One can make changes via I<sup>2</sup>C commands. If selected to indicate a temperature warning, CLIP\_OTW pin assertion occurs when the die temperature reaches warning level 1 as shown in the electrical specifications. The OTW has three temperature thresholds with a 10°C hysteresis. I<sup>2</sup>C register 0x04 indicates each threshold in bits 5, 6, and 7. The device still functions until the temperature reaches the OTSD threshold, at which time the outputs go into Hi-Z mode and the device asserts the FAULT pin. I<sup>2</sup>C is still active in the event of an OTSD, and one can read the registers for faults, but all audio ceases abruptly. After the OTSD resets, one can turn the device back on through I<sup>2</sup>C. The OTW indication remains until the temperature drops below warning level 1. The thermal foldback decreases the channel gain.
- 6. Undervoltage (UV) and Power-on-Reset (POR) The undervoltage (UV) protection detects low voltages on PVDD, AVDD, and CP. In the event of an undervoltage, the device asserts the FAULT pin and updates the I<sup>2</sup>C registerd, depending on which voltage caused the event. Power-on reset (POR) occurs when PVDD drops low enough. A POR event causes the I<sup>2</sup>C to go into a high-impedance state. After the device recovers from the POR event, the device re-initialization occur via I<sup>2</sup>C.

#### Feature Descption (continued)

Overvoltage (OV) and Load Dump — The OV protection detects high voltages on PVDD. If PVDD reaches
the overvoltage threshold, the device asserts the FAULT pin iand updates the I<sup>2</sup>C register. The device can
withstand 50-V load-dump voltage spikes.

#### 7.3.7 I<sup>2</sup>C Serial Communication Bus

The device communicates with the system processor via the  $I^2C$  serial communication bus as an  $I^2C$  slave-only device. The processor can poll the device via  $I^2C$  to determine the operating status. All reports of fault conditions and detections are via  $I^2C$ . There are also numerous features and operating conditions that one can set via  $I^2C$ .

The  $I^2C$  bus allows control of the following configurations:

- Independent gain control of each channel. The gain can be set to 12 dB, 20 dB, 26 dB, and 32 dB.
- Select the AM non-interference switching frequency
- Select the functionality of the OTW\_CLIP pin
- Enable or disable the dc-detect function with selectable threshold
- Place a channel in Hi-Z (switching stopped) mode (mute)
- Select tweeter detect, set the detection threshold, and initiate the function
- Initiate the open- and shorted-load diagnostic
- Reset faults and return to normal switching operation from Hi-Z mode (unmute)

In addition to the standard SDA and SCL pins for the I<sup>2</sup>C bus, the TAS5414C includes a single pin that allows up to four devices to work together in a system with no additional hardware required for communication or synchronization. The I2C\_ADDR pin sets the device in master or slave mode and selects the I<sup>2</sup>C address for that device. Tie I2C\_ADDR to DGND for master, to 1.2 Vdc for slave 1, to 2.4 Vdc for slave 2, and to D\_BYP for slave 3. The OSC\_SYNC pin is for synchronizing the internal clock oscillators, thereby avoid beat frequencies. One can apply an external oscillator to this pin for external control of the switching frequency.

| I2C_ADDR VALUE | I2C_ADDR PIN CONNECTION  | I <sup>2</sup> C ADDRESSES |
|----------------|--|----------------------------|
| 0 (OSC MASTER) | To SGND pin  | 0xD8/D9                    |
| 1 (OSC SLAVE1) | 35% DVDD (resistive voltage divider between D_BYP pin and SGND pin) $^{(1)}$ | 0xDA/DB                    |
| 2 (OSC SLAVE2) | 65% DVDD (resistive voltage divider between D_BYP pin and SGND pin) $^{(1)}$ | 0xDC/DD                    |
| 3 (OSC SLAVE3) | To D_BYP pin   | 0xDE/DF                    |

#### Table 1. Table 7. I2C\_ADDR Pin Connection

(1) TI recommends  $R_{I2C ADDR}$  resistors with 5% or better tolerance.

TEXAS INSTRUMENTS

www.ti.com.cn

## 7.3.8 I<sup>2</sup>C Bus Protocol

The TAS5414C has a bidirectional serial control interface that is compatible with the Inter IC (I<sup>2</sup>C) bus protocol and supports 400-kbps data transfer rates for random and sequential write and read operations. This is a slave-only device that does not support a multimaster bus environment or wait-state insertion. The control interface programs the registers of the device and reads device status.

The I<sup>2</sup>C bus employs two signals, SDA (data) and SCL (clock), to communicate between integrated circuits in a system. Data transfer on the bus is serial, one bit at a time. The transfer of address and data is in byte (8-bit) format with the most-significant bit (MSB) transferred first. In addition, the receiving device acknowledges each byte transferred on the bus with an acknowledge bit. Each transfer operation begins with the master device driving a start condition on the bus and ends with the master device driving a stop condition on the bus. The bus uses transitions on the data terminal (SDA) while the clock is HIGH to indicate a start and stop conditions. A HIGH-to-LOW transition on SDA indicates a start, and a LOW-to-HIGH transition indicates a stop. Normal databit transitions must occur within the low time of the clock period. Figure 12 shows these conditions. The master generates the 7-bit slave address and the read/write bit to open communication with another device and then wait for an acknowledge condition. The TAS5414C holds SDA LOW during the acknowledge-clock period to indicate an acknowledgment. When this occurs, the master transmits the next byte of the sequence. Each device is addressed by a unique 7-bit slave address plus R/W bit (1 byte). All compatible devices share the same signals via a bidirectional bus using a wired-AND connection. There must be an external pullup resistor for the SDA and SCL signals to set the HIGH level for the bus. There is no limit on the number of bytes that one can transmit between start and stop conditions. When the last word transfers, the master generates a stop condition to release the bus.

#### Figure 12. Typical I<sup>2</sup>C Sequence

Use the I2C\_ADDR pin (pin 2) to program the device for one of four addresses. These four addresses are licensed I<sup>2</sup>C addresses and do not conflict with other licensed I<sup>2</sup>C audio devices. To communicate with the TAS5414C, the I<sup>2</sup>C master uses addresses shown in Figure 12. Transmission of read and write data can be via single-byte or multiple-byte data transfers.

#### 7.3.9 Hardware Control Pins

There are four discrete hardware pins for real-time control and indication of device status.

- FAULT pin: This active-low open-drain output pin indicates the presence of a fault condition that requires the device to go into the Hi-Z mode or standby mode. On assertion of this pin, the device has protected itself and the system from potential damage. One can read the exact nature of the fault via I<sup>2</sup>C with the exception of PVDD undervoltage faults below POR, in which case the I<sup>2</sup>C bus is no longer operational. However, the fault is still indicated due to FAULT pin assertion.
- CLIP\_OTW pin: Configured via I<sup>2</sup>C, this active-low open-drain pin\ indicates one of the following conditions: overtemperature warning, the detection of clipping, or the logical OR of both of these conditions. During tweeter detect diagnostics, assertion of this pin also occurs when a tweeter is present. If overtemperature warning is set, the device can also indicate thermal foldback on this pin.
- 3. MUTE pin: This active-low pin is used for hardware control of the mute-unmute function for all four channels. Capacitor C<sub>MUTE</sub> controls the time constant for the gain ramp needed to produce a pop- and click-free mute function. For pop- and click-free operation, implementation of the mute function should be through I<sup>2</sup>C commands. The use of a hard mute with an external transistor does not ensure pop- and click-free operation, and TI does not recommended it except as an *emergency hard mute* function in case of a loss of I<sup>2</sup>C control. Sharing the C<sub>MUTE</sub> capacitor between multiple devices is disallowed.
- 4. STANDBY pin: On assertion of this active-low pin, the device goes into a complete shutdown, and the typical current-draw limit is 2 μA, typical. STANDBY can be used to shut down the device rapidly. If all channels are in Hi-Z, the device enters standby in approximately 1 ms. All I<sup>2</sup>C register content is lost and the I<sup>2</sup>C bus goes into the high-impedance state on assertion of the STANDBY pin.

#### 7.3.10 AM Radio Avoidance

To reduce interference in the AM radio band, the device has the ability to change the switching frequency via I<sup>2</sup>C commands. Table 2 lists the recommended frequencies. The fundamental frequency and its second harmonic straddle the AM radio band listed. This eliminates the tones that can be present due to demodulation of the switching frequency by the AM radio.

| U   | IS  | EURO                  | PEAN                            |
|---|-----|-----------------------|---------------------------------|

#### 7.4.1 Audio Shutdown and Restart Sequence

The gain ramp of the filtered output signal and the updating of the I<sup>2</sup>C registers correspond to the MUTE pin voltage during the ramping process. The value of the external capacitor on the MUTE pin dictates the length of time that the MUTE pin takes to complete its ramp. With the default 220-nF capacitor, the turnon common-mode ramp takes approximately 26 ms and the gain ramp takes approximately 76 ms.

Figure 14. Timing Diagram for Latched-Global-Fault Shutdown and Restart (UV Shutdown and Recovery)

#### TEXAS INSTRUMENTS

## 7.5 Programming

#### 7.5.1 Random Write

As shown in Figure 16, a random write or single-byte write transfer begins with the master device transmitting a start condition followed by the I<sup>2</sup>C device address and the read/write bit. The read/write bit determines the direction of the data transfer. For a single-byte write data transfer, the read/write bit is a 0. After receiving the correct I<sup>2</sup>C device address and the read/write bit, the device responds with an acknowledge bit. Next, the master transmits the address byte or bytes corresponding to the internal memory address being accessed. After receiving the address byte, the device again responds with an acknowledge bit. Next, the master device transmits the data byte to be written to the memory address being accessed. After receiving the data byte to be written to the memory address being accessed. After receiving the data byte, the TAS5414C again responds with an acknowledge bit. Finally, the master device transmits a stop condition to complete the single-byte write transfer.

Figure 16. Random-Write Transfer

### 7.5.2 Sequential Write

A sequential write transfer is identical to a single-byte data-write transfer except for the transmisson of multiple data bytes by the master device to TAS5414C as shown in Figure 17. After receiving each data byte, the device responds with an acknowledge bit and automatically increments the I<sup>2</sup>C subaddress by one.

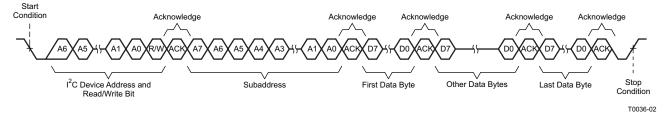

Figure 17. Sequential Write Transfer

#### **Programming (continued)**

#### 7.5.3 Random Read

As shown in Figure 18, a random read or single-byte read transfer begins with the master device transmitting a start condition followed by the I<sup>2</sup>C device address and the read/write bit. For the single-byte read transfer, the master device transmits both a write followed by a read. Initially, a write transfers the address byte or bytes of the internal memory address to be read. Thus, the read/write bit is a 0. After receiving the address and the read/write bit, the TAS5414C responds with an acknowledge bit. In addition, after sending the internal memory address byte or bytes, the master device transmits another start condition followed by the device address and the read/write bit again. This time the read/write bit is a 1, indicating a read transfer. After receiving the address and the read/write bit, the device again responds with an acknowledge bit. Next, the TAS5414C transmits the data byte from the memory address being read. After receiving the data byte, the master device transmits a not-acknowledge followed by a stop condition to complete the single-byte read transfer.

Figure 18. Random Read Transfer

#### 7.5.4 Sequential Read

A sequential read transfer is identical to a single-byte read transfer except for the transmission of multiple data bytes by the TAS5414C to the master device as shown in Figure 19. Except for the last data byte, the master device responds with an acknowledge bit after receiving each data byte and automatically increments the I<sup>2</sup>C subaddress by one. After receiving the last data byte, the master device transmits a not-acknowledge followed by a stop condition to complete the transfer.

## 8 Application and Implementation

#### NOTE

Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI's customers are responsible for determining suitability of components for their purposes. Customers should validate and test their design implementation to confirm system functionality.

#### 8.1 Application Information

The TAS5414C is a four-channel Class-D audio amplifier designed for use in head units and external amplifier modules. The device incorporates all the functionality needed to perform in the demanding OEM applications area.

## 8.2 Typical Application

Figure 36 shows a typical application circuit for the TAS5414C.

### **Typical Application (continued)**

#### 8.2.1 Design Requirements

Power Supplies

The device needs only a single power supply compliant with the recommended operation range. The device is designed to work with either a vehicle battery or regulated boost power supply.

Communication

The device communicates with the system controller with both discrete hardware control pins and with  $I^2 C$ . The device is an  $I^2 C$  slave and thus requires a master. If a master  $I^2 C$ -compliant device is not present in the system, it is still possible to use the device, but only with the default settings. Diagnostic information is limited to the discrete reporting FAULT pin.

External Components

Table 24 lists the components required for the device.

| EVM Designator                               | Quanity | Value                | Size                | Description                      | Use in Application                |

| Table 24. Supporting Comp |
|---------------------------|
|---------------------------|

## 8.2.2 Detailed Design Procedure

#### 8.2.2.1 Hardware and Software Design

- Step 1: Hardware Schematic Design: Using the Typical Application Schematic as a guide, integrate the hardware into the system schematic.
- Step 2: Following the recommended layout guidelines, integrate the device and its supporting components into the system PCB file.
- Step 3: Thermal Design: The device has an exposed thermal pad which requires proper soldering. For more
  information, see the Semiconductor and IC Package Thermal Metrics, SPRA953, and the PowerPAD
  Thermally Enhanced Package, SLMA002G, application reports.
- Step 4: Develop software: The EVM User's Guide has detailed instructions for how to set up the device, interpret diagnostic information, and so forth. For information about control registers, see the *Table 7* section.
- For questions and support go to the E2E forums.

## 8.2.2.2 Parallel Operation (PBTL)

The device can drive more current by paralleling BTL channels on the load side of the LC output filter. Parallel operation requires identical I<sup>2</sup>C settings for any two paralleled channels in order to have reliable system performance and even power dissipation on multiple channels. For smooth power up, power down, and mute operation, the same control commands (such as mute, play, Hi-Z, and so on) should be sent to the paralleled channels at the same time. The device also supports load diagnostics for parallel connection. There is no support for paralleling on the device side of the LC output filter, which can result in device failure. When paralleling channels, use the parallel BTL I<sup>2</sup>C control bits in register 0x0D. Parallel channels 1 and 2, and/or channels 3 and 4. Setting these bits allows the thermal foldback to react on both channels equally. Provide the audio input to channel 2 if paralleling channels 1 and 2, and channel 3 if paralleling channels 3 and 4.

### 8.2.2.3 Input Filter Design

For the TAS5414C device, the IN\_M pin should have an impedance to GND that is equivalent to the parallel combination of the input impedances of all IN\_P channels combined, including any source impedance from the previous stage in the system design. For example, if each of the four IN\_P channels have a 1- $\mu$ F dc blocking capacitor, 1 k $\Omega$  of series resistance due to an input RC filter, and 1 k $\Omega$  of source resistance from the DAC supplying the audio signal, then the IN\_M channel should have a 4- $\mu$ F capacitor in series with a 500- $\Omega$  resistor to GND (4 × 1  $\mu$ F in parallel = 4  $\mu$ F; 4 × 2 k $\Omega$  in parallel = 500  $\Omega$ ).

#### 8.2.2.4 Amplifier Output Filtering

The output FETs drive the amplifier outputs in an H-bridge configuration. These transistors are either fully off or on. The result is a square-wave output signal with a duty cycle that is proportional to the amplitude of the audio signal. The amplifier outputs require a low-pass filter to filter out the PWM modulation carrier frequency. People frequently call this filter the L-C filter, due to the presence of an inductive element L and a capacitive element C to make up the 2-pole low-pass filter. The L-C filter attenuates the carrier frequency, reducing electromagnetic emissions and smoothing the current waveform which the load draws from the power supply. See the *Class-D LC Filter Design* application report, SLOA119, for a detailed description on proper component selection and design of an L-C filter based upon the desired load and response.

#### 8.2.2.5 Line Driver Applications

In many audio applications, the end user would like to use the same head unit to drive either a speaker (with several ohms of impedance) or an external amplifier (with several kilohms of impedance). The design is capable of supporting both applications; however, the one must design the output filter and system to handle the expected output load conditions.

#### 8.2.3 Application Curves

### 9 Power Supply Recommendations

A car battery that can have a large voltage range most commonly provides the power for the device. PVDD is a filtered battery voltage, and it is the supply for the output FETS and the low-side FET gate driver. The supply for the high-side FET gate driver comes from a charge pump (CP). The charge pump supplies the gate-drive voltage for all four channels. AVDD, provided by an internal linear regulator powers the analog circuitry. This supply requires 0.1- $\mu$ F, 10-V external bypass capacitor at the A\_BYP pin. TI recommends not connecting any external components except the bypass capacitor to this pin. DVDD, which comes from an internal linear regulator, powers the digital circuitry. The D\_BYP pin requires a 0.1- $\mu$ F, 10-V external bypass capacitor. TI recommends not connecting any external not connecting any external components except the bypass capacitor to this pin.

The TAS5414C can withstand fortuitous open-ground and -power conditions. Fortuitous open ground usually occurs when a speaker wire shorts to ground, allowing for a second ground path through the body diode in the output FETs. The diagnostic capability allows debugging of the speakers and speaker wires, eliminating the need to remove the amplifier to diagnose the problem.

### 10 Layout

#### 10.1 Layout Guidelines

- The EVM layout optimizes for low noise and EMC performance.
- The TAS5414C device has a thermal pad up, therefore a the layout must take into account an external heatsink.
- Layout also affects EMC performance.
- The EVM PCB illustrations form the basis for the layout discussions.

#### 10.2 Layout Example

The areas indicated by the label "A", are critical to proper operation and EMC layout. The PVDD and ground decoupling capacitors should be close to the device. These decoupling capacitors must be on both groups of PVDD pins to ground. The ground connections of the snubber circuits must also be close to the grounds of the device. The grounds of the decoupling caps and the snubber circuits do not pass through vias before connecting to the device ground. This reduces the ground impedance for EMC mitigation.

Figure 39. Top Layer

### Layout Example (continued)

The area referenced as "B" are nets in the PCB layout that have large high frequency switching signals. These should be buried on an inner layer with ground planes on layers above and below to mitigate EMC.

Figure 40. A Mid Layer

### Layout Example (continued)

The bottom layer in the EVM is almost all ground plane. It can be seen that the other layers have ground planes that fill unused areas. All these ground planes need to be connected together through many vias to reduce the impedance between the ground layers. This allows for reduced EMI.

Figure 41. Bottom Layer

#### 10.3 Thermal Consideration

The design of the thermally augmented package is for interface directly to heat sinks using a thermal interface

compound (for example, Arctic Silver, Ceramique thermal compound). The heat sink then absorbs heat from the ICs and couples it to the local air. With proper thermal management this process can reach equilibrium at a lower temperature and heat can be continually removed from the ICs. Because of the device efficiency, heat sinks can be smaller than those required for linear amplifiers of equivalent performance.

R<sub>0.IA</sub> is a system thermal resistance from junction to ambient air. As such, it is a system parameter with the following components:

- $R_{\theta JC}$  (the thermal resistance from junction to case, or in this case the heat slug)
- Thermal resistance of the thermal grease
- Thermal resistance of the heat sink

One can calculate the thermal resistance of the thermal grease from the exposed heat slug area and the manufacturer's value for the area thermal resistance of the thermal grease (expressed in °C-in<sup>2</sup>/W or °C-mm<sup>2</sup>/W). The area thermal resistance of the example thermal grease with a 0.001-inch (0.0254-mm) thick layer is about 0.007°C-in<sup>2</sup>/W (4.52°C-mm<sup>2</sup>/W). The approximate exposed heat slug size is as follows:

64-pin QFP

Dividing the example area thermal resistance of the thermal grease by the area of the heat slug gives the actual resistance through the thermal grease:

64-pin QFP

0.07°C/W

The thermal resistance of thermal pads is generally considerably higher than a thin thermal-grease layer. Thermal tape has an even higher thermal resistance and should not be used at all. The heat-sink vendor generally predicts heat sink thermal resistance, either modeled using a continuous-flow dynamics (CFD) model, or measured.

Thus, for a single monaural channel in the IC, the system  $R_{\theta,JA} = R_{\theta,JC}$  + thermal-grease resistance + heat-sink resistance.

Table 25 indicates modeled parameters for one device on a heat sink. The junction temperature setting is at 115°C while delivering 20 watts per channel into 4- $\Omega$  loads with no clipping. The assumed thickness of the thermal grease is about 0.001 inches (0.0254 mm).

| _                                    |            |  |  |  |  |
|--------------------------------------|------------|--|--|--|--|
| DEVICE                               | 64-PIN QFP |  |  |  |  |
| Ambient temperature                  | 25°C       |  |  |  |  |
| Power to load                        | 20 W × 4   |  |  |  |  |
| Power dissipation                    | 1.9 W × 4  |  |  |  |  |
| ∆T inside package                    | 7.6°C      |  |  |  |  |
| $\Delta T$ through thermal grease    | 0.46°C     |  |  |  |  |
| Required heatsink thermal resistance | 10.78°C/W  |  |  |  |  |
| Junction temperature                 | 115°C      |  |  |  |  |
| System R <sub>0JA</sub>              | 11.85°C/W  |  |  |  |  |
| $R_{\theta JA}$ × power dissipation  | 90°C       |  |  |  |  |

#### Table 25. QFP Package Modeled Parameters

#### 10.4 Electrical Connection of Heat Slug and Heat Sink

Electrically connect the heat sink attached to the heat slug of the device to GND, or leave it floating. Do not connect the heat slug to any other electrical node.

#### **10.5 EMI Considerations**

EMI performance depends on both careful integrated circuit design and good system-level design. Controlling sources of electromagnetic interference (EMI) was a major consideration in all aspects of the design.

**TAS5414C** 

ZHCSFW8-DECEMBER 2016

### EMI Considerations (接下页)

The design has minimal parasitic inductances due to the short leads on the package. This dramatically reduces the EMI that results from current passing from the die to the system PCB. Each channel also operates at a different phase. The phase between channels is I<sup>2</sup>C selectable to either 45° or 180°, to reduce EMI caused by high-current switching. The design also incorporates circuitry that optimizes output transitions that cause EMI.

<sup>(1)</sup> The marketing status values are defined as follows:

ACTIVE: Product device recommended for new designs.

LIFEBUY: TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.

NRND: Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.

**PREVIEW:** Device has been announced but is not in production. Samples may or may not be available.

**OBSOLETE:** TI has discontinued the production of the device.

<sup>(2)</sup> RoHS: TI defines "RoHS" to mean semiconductor products that are compliant with the current EU RoHS requirements for all 10 RoHS substances, including the requirement that RoHS substance do not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, "RoHS" products are suitable for use in specified lead-free processes. TI may reference these types of products as "Pb-Free".

**RoHS Exempt:** TI defines "RoHS Exempt" to mean products that contain lead but are compliant with EU RoHS pursuant to a specific EU RoHS exemption.

Green: TI defines "Green" to mean the content of Chlorine (CI) and Bromine (Br) based flame retardants meet JS709B low halogen requirements of <= 1000ppm threshold. Antimony trioxide based flame retardants must also meet the <= 1000ppm threshold requirement.

<sup>(3)</sup> MSL, Peak Temp. - The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

<sup>(4)</sup> There may be additional marking, which relates to the logo, the lot trace code information, or the environmental category on the device.

<sup>(5)</sup> Multiple Device Markings will be inside parentheses. Only one Device Marking contained in parentheses and separated by a "~" will appear on a device. If a line is indented then it is a continuation of the previous line and the two combined represent the entire Device Marking for that device.

<sup>(6)</sup> Lead finish/Ball material - Orderable Devices may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead finish/Ball material values may wrap to two lines if the finish value exceeds the maximum column width.
